Diagnostic Supervisor release notes V5.3

A buffer in show device was increased to 256 characters.

Channel services was fixed to disable interrupts before releasing the vectors and the INVALIDATE function made to work.

SET MM ON, SET MM OFF, and SHOW MM commands were added to enable and disable memory management. At the same time DS$MMON and DS$MMOFF were modified to prevent the program from disabling memory management if the operator enabled it.

SYS$SETIMR and SYS$CANTIM were enhanced to change mode to kernel before doing MTPR's or disabling interrupts. This resolved some problems caused by interrupting programs that had set the processor mode to user.

Cleanup was enhanced to reset memory management and re-initialize the SCB after the program cleanup is complete.

Dummy entry points were added to $DS_DSSDEF and the entry vectors to accomodate SYS$LKWSET, SYS$SETAST, SYS$SETPRI, SYS$SETRWM, SYS$ULKPAG, SYS$ULWSET.

SYS$FAO used in stand-alone was modified to fix problems with !*? directives.

The known device data base was updated to include DL11, LP25, RX02, RX211, TM78, TS04, TS11, TU58, and TU78 support. The descriptor for KA780 has changed, the optional arguments are now G-floating, H-floating, WCS last address, and accelerator type.

An error is now generated if the processor type specified in the system identification register is not 1, indicating an 11/780.

Error text and status codes are returned if the supervisor is run from a command file. The next release will support running in batch.

DS$LOAD has been enhanced to allow programs to read parts of files indicated by the starting block number argument. The name of the console storage device is now always CSan.

The count of loops on subtests has been fixed to correctly reflect the number of passes thru the specified subtest.

The logout for SBI WRITE timeouts now includes the timeout address register.

The ABORT command and DS$ABORT now reset the stacks and reset the processor mode before doing program cleanup.

Diagnostic Supervisor release notes V5.4

Release 5.4 of the diagnostic supervisor has been made. ESSAA.EXE 5.4;214 and ECSAA.EXE 5.4;121 represent 11/780 and 11/750 supervisors. Relevent files can be found on PROTO 3 in Tewksbury as follows:

```
SYS$LIBRARY:DIAG.MLB;611
[DS]ESSAA.EXE;214     11/780 STAR supervisor
[DS]ECSAA.EXE;121     11/750 COMET supervisor
[DS]EVQDB.EXE         QIO driver for RP04,5,6
[DS]EVQDL.EXE         QIO driver for RL02
[DS]EVQDR.EXE         QIO driver for RM80,RP07,RM03,RM05
[DS]EVQDM.EXE         QIO driver for RK06,RK07
[DS]EVQXF.EXE         QIO driver for DR780
[DS]EVQTM.EXE         QIO driver for TM03/TE16,TU77,TU45
[DS]EVQTS.EXE         QIO driver for TS11
[DS]DIAGBOOT.EXE      Secondary Bootstrap
```

Please use these components in testing programs. Needless to say if any problems are encountered please report them to me immediately so their solutions can be included in the next release.

Release notes

- Support for drivers was upgraded to reflect VMS 2.0 interface changes. Loadable drivers have been re-released to reflect Release 2.0 of VMS.
- The supervisor can be run from a VMS command proceedure. When the supervisor is running under VMS it uses RMS to access SYS$INPUT and SYS$OUTPUT.
- Bug fixed to remove supervisor error when supervisor is started again after interrupting a script.
- The APT interface will now generate an error if no PTEXT is found when a process PTEXT command is given.
- A buffer in show device was increased to 256 characters.
- Internal processor registers can be examined with EXAMINE Pxx, where xx is a register number in the current radix. If only the decimal values are available Try EX P%D127 to get register ^X7F. Internal registers can be changed with the DEPOSIT command.
- Channel services was fixed to disable interrupts before releasing the vectors and the INVALIDATE function made to work. Also SETMAP now sets and clears all map registers and allows all to be used for transfers.
- Support was added for the RL02 as a boot device.
- Time conversion routines were changed to fix loss of precision in hundredths.
- SET MM ON, SET MM OFF, and SHOW MM commands were added to enable and disable memory management. At the same

time DS$MMON and DS$MMOFF were modified to prevent the program from disabling memory management if the operator enabled it. Also the return code in R0 now indicates the previous state of memory management and an error return if DS$MMOFF was trying to disable memory management and the operator had enabled it. If memory management is enabled the stack for each mode is write protected against lower access modes.

- DS$ASKSTR now returns 0 in R1 if the default answer was given to a query.

- SYS$SETIMR and SYS$CANTIM were enhanced to change mode to kernel before doing MTPR's or disabling interrupts. This resolved some problems caused by interrupting programs that had set the processor mode to user.

- Cleanup was enhanced to reset memory management and re-initialize the SCB after the program cleanup is complete.

- Corrected errors induced when more the 2 megabyte of memory was present.

- Dummy entry points were added to $DS_DSSDEF and the entry vectors to accomodate SYS$LKWSET, SYS$SETAST, SYS$SETPRI, SYS$SETRWM, SYS$ULKPAG, SYS$ULWSET.

- SYS$FAO used in stand-alone was modified to fix problems with !*? directives.

- The known device data base was updated to include DL11, LP25, RX02, RX211, TM78, TS04, TS11, TU58, and TU78 support. The descriptor for KA780 has changed, the optional arguments are now G-floating, H-floating, WCS last address, and accelerator type.

- An warning is now generated if the processor type specified in the system identification register is not correct.

- DS$LOAD has been enhanced to allow programs to read parts of files indicated by the starting block number argument. The name of the console storage device is now always CSan.

- The count of loops on subtests has been fixed to correctly reflect the number of passes thru the specified subtest.

- The logout for SBI WRITE timeouts now includes the timeout address register.

- The processor mode and and all stacks and registers are now reset before the users cleanup code is executed.

1.0 BUFFERED I/O SUPPORT

The supervisor now includes support for QIO drivers using buffered I/O (such as line printers).

2.0 HELP FACILITY

The new Supervisor includes a HELP facility. It is invoked via the "HELP" command. In general it is identical functionally with the VMS HELP command. Additionally, it supports gathering HELP on diagnostics via typing the diagnostic code (ES, EV, EC pre-fix followed by diagnostic name, as "EVRAA", etc.) as the first keyword after HELP (e.g., "HELP EVRAA"). In standalone mode the HELP command will function off of any load media (including magtape and console media). In user mode however, it will not function from magtape or the console media, as these are not fully supported by VMS RMS (see below, description of Supervisor RMS).

3.0 LOAD AND SCRIPT

The Supervisor LOAD (which loads files for the commands RUN and LOAD as well as for diagnostics via the $DS_LOAD service call) and SCRIPT file handling services have been modified to use RMS file services.

4.0 MAGTAPE

The supervisor now supports magtape (TM03 only) as load media. TS-11 and TU-78 will be supported in a future release.

5.0 RMS IMPLEMENTATION

The diagnostic supervisor implementation of RMS is similar to the VMS implementation, but is specifically adapted to the standalone DS environment.

DISCLAIMER

Since there are currently no diagnostics which use RMS services, we can not guarantee 100% functionality of RMS code, though we have attempted thorough QA testing. However, services within the Supervisor which use RMS will function correctly.

Console Device Naming

Previous to release 6.0, due to a file name-handling loophole in the file load routine,

it was possible to specify the console device as "CS:". This is not consistent with Supervisor convention, which requires complete device names (i.e., "DMA0:" not "DM:" even if only one RK06/07 is attached). In Version 6.0, "CS:" will not function on COMET (11/730); it will fail when the TU58 driver attempts to access a non-existent drive. The solution is that full device names MUST be typed. In future versions of the Supervisor, this naming "loophole" will be closed, and omitting the controller letter or drive number in the console device specification will return an illegal device error (RMS$_DEV).

5.1 User Mode

To consistently support RMS in user mode (where RMS calls are passed through to VMS), the Supervisor SET LOAD command will function correctly in user mode (as will SHOW LOAD). This is done by translating or reassigning SYS$DISK for device names, and via an RMS housekeeping routine to alter default directory. The Supervisor exit handling routine will restore the original values: however for this to occur, the Supervisor must be terminated either by ^Z or by a ^Y, EXIT sequence. If the (VMS) STOP command is used, the original default directory is not (and CAN not be) restored.

5.2 Differences Between DS RMS And VMS RMS

Supervisor RMS functionality not duplicated by VMS:

- Supervisor RMS supports files on the console media (floppy or TU-58). These files are in RT-11 format, but the Supervisor RMS $GET facility will provide file records as if the file were an ODS CR-attribute, variable length record file. The FAB's RFM field (FAB$B_RFM) will have the value 4.

- Random by RFA (record's file address) access is supported for magtape as well as for conventionally random-access devices. VMS does NOT support magtape random access. In general, random file access should not be used by any level 2 diagnostic, since if the load device is magtape, the function is unsupported in user mode.

VMS RMS functionality not duplicated by Supervisor:

- The Supervisor does not support NAM blocks in any form.

- The Supervisor supports only one form of XAB (the FHC XAB, returning file header characteristics). Any other XAB in the FAB's XAB chain will be ignored, though no error will result. This is because the information is not meaningfull in the diagnostic environment.

- In the FHC XAB, the LRL (longest actual record length) field is not supported. It is meaningful only for ODS files in any case. It will be set to maximum record length always.

- Only sequential files are supported. An attempt to open a file with INDEX or RELATIVE organization results in error RMS$_ORG (illegal file organization).

- Only READ-type functions are supported, since the supervisor does not support write access to any media. To be specific, the functions which the Supervisor RMS package implements is:

  1. $OPEN (access a file on media and initialize FAB)

  2. $CONNECT (Define a record stream for access to a file, initialize RAB)

  3. $GET (Copy a record within the file to a user buffer)

  4. $READ (Unformatted read from file, beginning on block boundary)

  5. $DISCONNECT (Close out a record stream)

  6. $CLOSE (Close out any record streams associated with FAB, and de-access file attached to FAB)

- The bits in the FOP and ROP fields are not significant, except for the BIO bit in the ROP field (specifying block I/O via the $READ call).

- Asynchronous file operations are not supported.

- RMS operations to the terminal are not supported.

- A user may have up to three files open simultaneously.

- Multibuffering and multiblocking are not supported.

- Random access by key or record number is not supported.

- The RAB TMO (time out) field is ignored.

6.0 BUG FIXES

The following Supervisor "bugs" have been fixed for the 6.0 release:

- Channel services incorrectly calculated the number of map registers required for a transfer.
- The operator request routine incorrectly defaulted parameters when prompting was disabled.
- The COMET machine check log-out was incorrect.

1.0 BUG FIXES

- BUG: "EXAMINE PSL" with "/WORD" or "/BYTE" would use only low-order bits of PSL, but the high-order fields would still be decoded and typed as 0.

  FIX: PSL is now unaffected by "/WORD" and "/BYTE"; it is always longword.

- BUG: Previous to Version 6.0, the console storage device could be specified by "CS:". This is at odds with Supervisor convention which requires full device name given in attach command. It results from an accidental "loophole" in that only the first two characters were checked, and an unspecified unit number was converted to 0. In Version 6.0, the unit number conversion was (also accidentally) removed, and using the "CS:" form to Version 6.0 causes a device error on COMET (the STAR console load routine does not use unit number) when the TU58 attempts to access a non-existant (negative) unit.

  FIX: The "CS:" short form is no longer allowed. It will result in an "invalid or illegal device" RMS error (RMS$_DEV) during name parsing. You must type the full device name (e.g., "CSA0:").

2.0 ENHANCEMENTS

- The Supervisor now supports a DIRECTORY command. The format is:

  ```
  DIRECTORY [device:][[directory]]
  ```

  Examples:

  ```
  DS> DIRECTORY DBB3:[SYSMAINT]
  DS> DIR MTA0:
  DS> DIR CSA0:
  DS> DIR [DS]
  DS> DIR DBB3:
  DS> DIR
  ```

  Device and directory default to the current load path (original default is "<load device>:[SYSMAINT]" or last SET LOAD specification). All load media are supported. The format is identical to the standard default VMS directory format. There are no qualifiers. Only file name and version (if applicable, i.e., not on RT-11 media) are typed, and there is no provision for typing dates, sizes, etc.

- To support the AUTOSIZER program, the supervisor's ATTACH command processor has been made externally callable. The entry point is DS$ATTACH

(cmdline,[prompt]) where cmdline is the address of a string descriptor for the ATTACH command to be parsed, and prompt is the address of a descriptor for a buffer (MUST be at least 1 byte long if prompt is given!) to receive the ASCIC text with which to prompt the operator if the command line is incomplete or incorrect (on error, the prompt string is set, and the cmdline descriptor length is decreased to include only the correct part of the input line). The prompt argument is optional and in general is useless except within the Supervisor.

Format:

```
$DS_ATTACH (cmd, [pmt])          ! Bliss
$DS_ATTACH_x    cmd, [pmt]       ; Macro
```

o The Supervisor HELP routine has been made callable, to allow programs implementing a conversation mode to include a HELP command. You pass the address of a descriptor of a command string; this string is just what you'd type on a Supervisor HELP command line, except leave out the "HELP" keyword. You can access the program's usual HELP file (preferable) by prefixing whatever keys the operator types with the program name. Keep in mind that HELP will fiddle with the adapter and controller, etc., in the path to the load device.

Format:

```
$DS_HELP (keylst)                ! Bliss
$DS_HELP_x      keylst           ; Macro
```

o User control of ^C

. In some diagnostics, it may be necessary to call DS services which do implicit "$DS_BREAK" calls during sections of code which must not be interrupted by "^C". To solve this problem, new functionality has been added to the $DS_CNTRLC service. A second argument, DISABL, has been implemented. The value of this argument defaults to "0", and the DS$CNTRLC routine accepts argment lists of only one argument to maintain compatibility with currently released diagnostics. If the low bit (bit 0) of DISABL is SET, ^C will be ignored by the Supervisor. If a user ^C handler is set, it will not be called, nor will the Supervisor itself take any special action beyond setting it's ^C flag bit. Note that if ^C recognition is disabled, and a ^C character is typed, the ^C will be honored as soon as ^C recognition is re-enabled. Therefore, the ^C is effectively postponed beyond the non-interruptable segment of code, but is not lost.

Format:

```
$DS_CNTRLC ([astadr], [disabl]) ! Bliss
```

```
$DS_CNTRLC      [astadr], [disabl]      ; Macro
```

. Previously, the user ^C handler routine had no value. Now, the user handler has the option of telling the Supervisor to handle the ^C normally even though there was a user handler defined. To do this, the user's handler should return a failure status code (R0 bit 0 clear). If the user handler returns a success code, the Supervisor will do nothing further.

o It is possible for messages to be typed out asynchronously, by AST routines for example. This typeout may occur while the operator is keying in commands and/or data. In such a circumstance, VMS will retype the input line automatically (as if a ^R had been typed), but the Supervisor would just let the line "dangle". Now, the Supervisor will perform the "^R"

3.0 NEW LOAD DEVICE SUPPORT

o Supervisor RMS (and therefore all Supervisor file utilities including HELP, DIRECTORY, DS$LOAD, RUN, and LOAD) now will function with the TS-11/TS-04 tape drive sub-system. This addition is transparent to users of the utilities, syntax and programming-wise.

- A user control-C handler returning failure status under APT would cause the Control-C to be ignored, since status information was cleared before the user routine was CALLed. This has been fixed by deferring the status clear.

- DIRECTORY - due to an inconsistency in string descriptor handling, access violations could occur during DIRECTORY depending on previous stack contents. Specifically, if a HELP command with keywords was entered previously, DIRECTORY would fail, but would succeed if HELP without any keywords was typed. The problem has been fixed.

NOTE

Addition to directions for DIRECTORY command:

1) In order to get a directory in user mode, the target device must be mounted (do NOT use the /FOREIGN qualifier!). You can not get a directory from the console device in user mode, since VMS RMS does not support it.

2) The target device must be attached before you can get a directory of it. This applies in both standalone AND user modes. This is due to the fact that the Supervisor does not enforce device naming conventions, and therefore requires access to a Ptable to figure out what type of directory structure it is accessing.

3) The directory command will not work on ODS structure level 1 disks in standalone. (This is a bug, and will be corrected in a future version of the Supervisor!)

1.0 BUG FIXES

- If the COMET supervisor is loaded from a Massbus device, it currently attaches the load MBA as RH0, irregardless of the actual unit number. In version 6.3, this has been fixed, and it will attach the correct unit number.

- In the $DS_DEVTYP macro, under certain circumstances the supervisor could be fooled into thinking that a device name string was part of a Ptable descriptor when it actually was only a name. This is because it looks 5 bytes beond the end of the string for a byte 80(x), and if the byte IS 80, the supervisor thinks it is a Ptable descriptor. This has been fixed by adding a null byte to the end of the DEVTYP string list. This does not affect any diagnostic already assembled as it is transparent to both diagnostic and supervisor, occuring only within the library DIAG.

- For the $DS_ABORT macro, there was a difference in syntax between the MACRO and BLISS forms, as BLISS required 'PROGRAM' while MACRO would accept PROGRAM or program. BLISS will now accept PROGRAM and program, as well as 'PROGRAM' for compatibility with older versions.

- The $DS_WAITMS macro has been fixed so it will work correctly.

- The DV11 is now ATTACH-able. Previously the Supervisor knew of the device but would not allow ATTACH-ing it.

- RMS fixes (to match VMS RMS functionality more closely):

  - When $GET returns RMS$_RTB, the RAB$L_STV field will contain the full record size.

  - $READ will return the block number read in the first longword of the RFA (RAB$L_RFA0). The byte offset of the RFA (RFA$W_RFA4) is 0.

- SBI silo register dump (11/780 only). Due to an incorrect assumption as to instruction context in indexed addressing mode, the wrong field was decoded for function ID. This problem has been corrected.

- A fix to DS$WAITUS to promote more correct and consistent behaviour. This involves ensuring that the interrupt and error bits in the timer CSR are cleared.

- It is now legal for a section name to include the characters "$" and "_". Previously, they could be used in a diagnostic section name definition, but the Supervisor /SECTION qualifier (RUN and START commands) would not recognize them as legal. The Supervisor will now accept these characters. In conjunction with this, the function code CLI$K_SYMBOL has been added to the $DS_CLIDEF macro, and may be used by any diagnostic. This code causes PARSE to recognize a string composed of the characters "A" to "Z", "a" to "z", "0" to "9", "$", and "_".

- In standalone, the $SETPRT service would return an incorrect

address vector. The start address would be 1FF hex, due to a reversal of operands in a BICL3 instruction. The address will now be correct.

o In standalone, the $DS_RELBUF (or $CNTREG) would fail with an ERRSUP (Supervisor fatal error) if the page geing released was in P1 or SYS space and had been modified with memory management on (M bit set in PTE). V6.3 corrects this problem.

2.0 ENHANCEMENTS

o Several QIO driver service entry points have been added to support level 2R to level 2 conversion: IOC$ALLOSPT, EXE$MAXACMODE, and EXE$READLOCK. These entry points are defined in the DIAG.MLB $DS_QIOVEC macro.

o Previous to V6.3, it was possible to attach a device to any of the predefined "main buses" recognised by the supervisor. Now, an error message will result if the main bus name does not match the CPU type; for example, if a device is attached to an SBI on a COMET processor the error message is "there is no SBI on this type processor." Also, two new "main bus" names have been defined. These can be used on any VAX implementation. They are PHAD (for "Physical Address Decoder") and HUB.

o The $DS_SETVEC macro (DS$SETVEC routine) now allows setting the processor mode in which an interrupt will be handled, without changing the handler address. To do this, set the SRVADR argument to 0, and use the CODE argument as usual. Bits 2 to 31 of the SCB vector will be unchanged, but bits 0 and 1 will still be set to CODE.

o New commands. These support customer service and manufacturing in using terminals narrower than 132 columns, without losing data.

- SET WIDTH n
- SHOW WIDTH

These commands will be accepted and carried out in user mode, but will have no effect on terminal characteristics (use VMS SET TERMINAL/WIDTH=n before running Supervisor). In standalone, a newline is forced when the cursor (printhead) passes column n.

o In user mode (only), the Supervisor will accept subdirectories in file specifications.

o HELP FILE: Where possible, I have included standard (fixed) CSR and vector addresses in the DEVICE portion of EVSAA.HLP. Also, the lines which used to read "Device:" now read "Description:" to avoid possible confusion over actual names. Finally, the recommended generic names have been brought into agreement with the "MASTER LIST OF PDP-11/VAX-11 DEVICE NAME CONVENTIONS" maintained by Kerby Altmann of VMS Development.

o Beginning with V6.3, the Supervisor .DOC file will contain a concatination of all release note files (from V5.3 on). This

will allow easier reference to warnings on use of Supervisor features, as well as tracking enhancements/bug fixes.

1.0 BUG FIXES

- QIO driver entry points IOC$ALLOSPT, EXE$MAXACMODE, and EXE$READLOCK, which were supposed to have appeared in version 6.3, somehow didn't. They are present in 6.4.

- ECSAA attached MASSbus load device incorrectly. This has been fixed.

- Most bits of the 11/750 UBI register are undefined, specified as MBZ (Must Be Zero) but are actually unpredictable. This is confusing in the output of a $DS_SHOWCHAN call. Therefore, the Supervisor will now mask out these undefined bits.

- The $SETPRT system service (standalone) would not work if the caller was not already in Kernel mode. Version 6.4 will do a CHMK to insure kernel mode privilege for the routine.

- The byte context PRVPRT output argument of $SETPRT was being written as a longword. Version 6.4 will write it as a byte.

- The diagnostic cleanup code was not called when a loop on subtest terminated. This has been fixed.

- If a range of tests were used with the /SUBTEST qualifier, the diagnostic would loop on the first subtest with the specified number, irregardless of which test it was in. Now, it will only loop on the correctly numbered subtest in the last test number given.

- The VMS console device non-interrupt I/O drivers have been incorporated into the Diagnostic Supervisor. This means console reads which fail due to media bad spots will be re-tried. (This is more of an enhancement, but is listed under bugs because Manufacturing has complained of trouble with console bad spots under APT control).

- The bliss diagnostic library (DIAG.L32) had several bugs in it, including incorrect macros for $DS_$INITIALIZE and $DS_$STRING, many errors in %ERROR statements to point out bad macro useage, and incorrect compilation of $DS_PRINTSIG macro. These have all been fixed.

- A bug in $DS_SETVEC prevented setting the mode in which a 'soft-vectored' exception was handled. Soft vectored exceptions include BPT and T-bit traps. This problem has been fixed.

2.0 ENHANCEMENTS

- FIELD definitions for all Ptable types known to the Supervisor have been added to the Bliss library (DIAG.L32). They can be used via the $DS_HPODEF macro; for example, "$DS_HPODEF ($DS_DZ11_DEF)" allows

access to the basic Ptable fields, plus the fields of the DZ11 Ptable. Also, literals representing the length of these Ptables have been added. There are no FIELD definitions for Ptables which have no device dependent fields.

- Correct spelling of many Supervisor messages, and change to mixed case for greater legibility.

3.0 MISCILLANEOUS

- Note: The $SETAST system service (as documented in the VMS System Service manual) is supported by the Supervisor in standalone. It was added in version 5.4 for Supervisor internal use and was not documented. It may be used by level 2 and 3 programs freely.

- Note: The Diagnostic Design Guide is in error over the PRINT ($DS_PRINTX, $DS_PRINTB, $DS_PRINTF) format argument. It should be counted ascii (ASCIC) not ASCID.

3.1 Previously Undocumented Gems Of Wisdom: Linking Diagnostics

- Bliss-32 => If a diagnostic is written entirely in Bliss-32, without any Macro-32 modules, the diagnostic must be linked with a DS.STB file defining Diagnostic Supervisor entry points (for system services, etc.).

  DS.STB can be created easily from the following Macro-32 source:

```
        .TITLE  DS.STB  Symbol table to link with BLISS modules
        .LIBRARY        'SYS$LIBRARY:DIAG'
        $DS_DSADEF      GLOBAL
        $DS_DSSDEF      GLOBAL
        .END
```

  And assembled/linked as follows:

```
        $ MACRO DS
        $ LINK/SYMBOL_TABLE=DS/NOEXECUTABLE DS
```

  Link <diag> as such:

```
        $ LINK <qualifiers> <diag>+DS.STB
```

- Macro-32 => The $DS_BGNMOD and $DS_ENDMOD macros use a label called $M0 for checking. The $DS_BGNMOD macro defines "$M0 == 0", and the $DS_ENDMOD defines "$M0 == $M0 + 1". Therefore, a missing $DS_BGNMOD macro will cause an "undefined symbol" error at assembly time in that

module, and a missing $DS_ENDMOD will cause a "multiply defined global" error at link time, due to the fact that correct module(s) define $M0 as 1 and modules missing $DS_ENDMOD macros define $M0 as 0.

RELEASE NOTES FOR
VAX-11 DIAGNOSTIC SUPERVISOR
VERSION 6.5
4-DEC-1981

A. GENERAL ENCHANCEMENTS

1. UNIBUS Mapping

The entire UNIBUS is now mapped, instead of just the I/O pages. This allows diagnostics to get UNIBUS NXM errors instead of access violation errors.

2. Channel Services status

By popular demand, channel services has been enhanced to return additional information:

- o UNIBUS NXM errors reported by bit CHS$M_BUSNXM
- o MASSbus writecheck errors reported by three bits:
  - a. CHS$M_CHNDPE is set if either of the other two are set:
  - b. CHS$M_MBAWCKLWR is set if the MASSbus write check lower bit is set.
  - c. CHS$M_MBAWCKUPR is set if the MASSbus write check upper bit is set.

3. APT troubleshooting

To enable troubleshooting of diagnostic problems under APT, the hardware context will not be initialized when an ABORT command code is received from APT, if errors have occurred.

4. Automatic diagnosis assistance

There are several programs (including APT, RD, and EVXBB) which act as operators to VDS. Currently, this process requires parsing of the VDS ASCII output. With Version 6.5, VDS is growing to make the task of automated diagnosis easier: A new flag has been implemented, called BINARY. When this flag is set, VDS will output a binary 'type byte' as the first byte of every message (including prompts and diagnostic PRINTS). This type byte will indicate the message class (e.g., command error, program start, harderror, etc.) The type codes are defined in macro $DS_TYPECODE in DIAG.MLB and DIAG.L32. Currently, the implementation is incomplete. Most messages for this release will have a type code of 0 (ds$k_type_general). Only prompts, program sequence messages (start, first_pass, end, etc.), and command messages will generate meaningfull type codes. The BINARY flag is off by default, and is not turned on by SET FLAGS ALL (or turned off by CLEAR FLAGS ALL).

5. DEVICE UNIQUENESS

The concept of a unique device has been altered. Previously two devices with the same name were considered the same, and could not be ATTACHed at the same time. To support network nodes

(which may be accessible through several different network adapters). TWO DEVICES WITH THE SAME NAME BUT DIFFERENT LINKS ARE NOW CONSIDERED DIFFERENT. This means that a device attached to the wrong adapter can not be 'edited' by re-attaching it. The new DEATTACH command gives the ability to correct any ATTACH errors.

6. Error messages

All error messages (ERRHARD, ERRSOFT, ERRDEV, ERRSYS, and "Software detected error") now include a trailing "End of error" line heralded by "********". This makes it easier to separate errors and assorted intervening text on printouts. It was particularly devised in conjunction with the BINARY flag (see item 4 in this section), and has its own unique type code.

B. COMMAND ENHANCEMENTS/ADDITIONS

1. New Qualifier /BRIEF

This qualifier can be used on the SHOW DEVICE and SHOW SELECT commands. It will cause only the device name and type fields to be printed.

2. New qualifier /ADAPTER=name

This qualifier can be used on the DEATTACH, SELECT, DESELECT, and SHOW DEVICE commands. It will limit the command to devices attached to the adapter with device name 'name'. E.g., for select, "SELECT/ADAPTER=DW0 ALL" will cause all devices attached to DW0 (but not devices attached in turn to those devices) to be selected for test. The special adapter name "HUB" is recognised, but not "SBI", "CMI", etc.

3. DEATTACH

This command reverses the ATTACH command for a device. It can be used to remove incorrectly attached devices. The /ADAPTER=name qualifier is REQUIRED on this command. Since Ptables are linked in a tree structure, it makes no sense to de-attach a device which has other devices attached to it, unless those devices are also de-attached. Therefore, the DEATTACH command will recursively "seek and destroy" all lower level devices for each device it de-attaches. E.g., if DW0 has devices DMA and TTA attached to it, TTA has device TTA0 attached to it and DMA has DMA0 attached to it, typing "DEATTACH/ADAPTER=HUB DW0" will cause DW0, DMA, TTA, DMA0, and TTA0 to be de-attached. a message will be typed for each as it is de-attached. (note that the message order may appear strange, since the de-attach routine does a post-order search).

4. EXIT

In on-line mode, this command will execute a VMS $EXIT system service to terminate the VDS image. In standalone, it will do a HALT after re-initializing the machine (a console CONTINUE will return to VDS command mode, however).

5. SHOW BASE

   Displays the current base value. (as in "SET BASE").

6. SHOW DEFAULT

   Displays the current default radix and data size.

7. SHOW SECTIONS

   Lists the SECTION names supported by the current diagnostic. An error results if no diagnostic is loaded.

8. SHOW STATUS

   Prints the name, revision, current time, error count, section, pass count, test, subtest, and PC for a CNTRL/C'd diagnostic. If there is not a running diagnostic, an error is typed.

9. SHOW SUPPORT

   Prints the list of devices supported by the current diagnostic. An error results if no diagnostic is loaded.

C. GENERAL CLI/PARSE ENHANCEMENTS

1. New PARSE features

   Special function codes have been added to PARSE to improve command parsing for the VDS CLI (they can also be used by diagnostics):

   o CLI$K_EOL: Accepts a string consisting of blanks (any number of spaces and/or tabs; including none of either) followed by either end of line (no more characters in string) or a "!" character (comment delimiter). It will call the action routine and branch through the miss label, as appropriate.

   o CLI$K_SLASH: Accepts blanks, followed by the character "/" followed by blanks.

   o CLI$L_COMMA: Like CLI$K_SLASH, but expects a "," instead of a "/".

   o CLI$K_VALUE: like CLI$K_SLASH, but expects either an "=" or a ":" instead of a "/". "=" and ":" are exactly equivalent (as in VMS DCL).

2. CLI improvements:

   o CLI uses the features listed above to make command syntax more flexible. For example, the qualifier "/PASSES:1" is the same as " / PASSES = 1".

   o The old CLI had two error messages: "Illegal command" and "Ambiguous command"; both of which were usually rather ambiguous themselves. The latter has been replaced by "Incomplete command" and the rules for generating each have

been tightened:

a. A command is illegal if something unexpected is found. E.g., the command "XYZZY".

b. A command is incomplete if something expected is NOT found. E.g., "CLEAR" lacking any arguments.

Furthermore, both error messages include some information on what was in error. "Illegal command" displays the command line UP THROUGH THE FIRST ILLEGAL CHARACTER. "Incomplete command" displays up to where the expected data should have been. E.g., the command "XYZZY" results in:

```
?? Illegal command
   \X\
```

while the command "CLEAR" results in:

```
?? Incomplete command line
   \CLEAR\
```

D. PTABLE DESCRIPTOR ENHANCEMENTS

1. New directives

o Previously, to request logical (yes/no) data, it was necessary to use the $DS_$STRING directive, supplying prompt, "NO", and "YES" strings. I have implemented the new directive $DS_$LOGICAL. It's only argument is the prompt string. This saves program space, and also allows ABBREVIATION of the words "Yes" and "No". All Ptable descriptors within VDS which require "Yes/No" input have been modified to use this directive.

o Value translation can now be accomplished by the directive $DS_$CASE. The argument is a list of "case_pairs"s. The current VALUE register is compared to the first value of each pair until a match is found; the second value of that pair becomes the new VALUE, and the case directive is exited. VALUE is not altered if no match is found.

Bliss-32:

```
$ds_$case (<1,%x'FFF'>, <2,%x'1CE0'>)
```

MACRO-32

```
$ds_$case <<1,<^xFFF>><2,<^x1CE0>>>
```

E. MISCELLANEOUS ENHANCEMENTS

1. VERIFY

VDS now supports a mechanism similar to the VMS "SET [NO]VERIFY". The flag VERIFY can be set or cleared via "SET FLAG VERIFY" or "CLEAR FLAG VERIFY". When the flag is set, commands read from VDS scripts are echoed to the console. When the flag

is clear, command lines are not echoed. This does not affect error or information messages, and has no effect unless commands are being processed from a VDS SCRIPT file : commands read from a VMS command file are considered by VDS to be coming from the console!

!!The flag is CLEAR by default!!

2. MIXED CASE MESSAGES

Many messages throughout VDS have been altered from all caps to mixed case. We feel that this is much easier to read, as well as appearing "warmer", in the line of "human engineering".

F. BUG FIXES

1. Ptable descriptor location

A bug has existed which could cause errors when a program's DEVTYP list existed but had 0 elements. This has been fixed.

2. ATTACH

It is now possible to CNTRL/C out of an ATTACH prompt. Furthermore, ATTACH will not attempt to prompt a SCRIPT or APT for a missing or invalid parameter: the command will be aborted. From a SCRIPT, the error "Prompt not found" is generated. From APT mode, a "Software detected error" is generated.

3. Fixes to DIAG.L32 macros

- $DS_ENDMOD malfunctioned when a module did not contain tests (incorrectly setting an overlayed PSECT which at runtime should contain highest test number). This has been fixed.
- $DS_HPO_DECL has been fixed to correctly accept multiple arguments.
- $DS_$STRING and $DS_$INITIALIZE did not function properly. Now they will.

4. Event flag services

All standalone event flag services have been re-written to correspond to the VMS services. The $SETEF and $CLREF services will return SS$_WASSET or SS$_WASCLR when they should, as will $READEF.

G AUTOMATED DIAGNOSTIC QUALITY ASSURANCE

G.1 Background

Enhancements have been made to the Diagnostic Supervisor to enable it to automatically perform Quality Assurance checks on diagnostic programs.

This version of the Supervisor performs the Normal Start check

(Section 3.1 in the "VAX Diagnostic Quality Assurance Checklist"), the Multiple Pass check (Section 3.2), the Loop on Test check (Section 3.7), and the Run Backwards check (Section 3.5). Other sections in the checklist will be added to the Supervisor as time and resources permit.

The Normal Start check does the following: saves the current setting of the Supervisor flags; turns on the TRACE flag; turns off the following flags: BELL, IE1, IE2, IE3, IES, LOOP, OPER, PROMPT, QUICK, and SEARCH; performs a normal start of the diagnostic program, running all the tests in the specified section; turns the TRACE flag off; and either stops when a QA error is detected or proceeds to the next check.

The types of errors that the Normal Start check will detect are asking for operator input when the no-default flag is set (in the $DS_ASK macro) and reporting a diagnostic error via one of the $DS_ERR macros. When a QA error is detected, the Supervisor will print out information that should help the diagnostic engineer determine why the program failed QA. Then, an overall error summary table is printed, the Supervisor flags are restored to their previous settings, and the diagnostic is aborted.

If the Normal Start check succeeds, the Multiple Pass check is performed. This check performs a number of passes of the diagnostic program. The current setting of the QAMULTIPLEPASS flag is the number of passes that will be executed (see Section G.4). The types of QA errors that can occur are the same as those in the Normal Start check.

If the Multiple Pass check succeeds, the Loop on Test check is executed. This check runs each test QATESTLOOPS times (see Section G.4). Assuming a diagnostic has tests 1, 2, and 3, and QATESTLOOPS has been set to 4, this check will run the initialization code, followed by tests 1, 1, 1, 1, 2, 2, 2, 2, 3, 3, 3, and 3. The types of QA errors that can occur are the same as those in the Normal Start check.

If the Loop on Test check succeeds, the Run Backwards test is executed. This check runs the tests in reverse order. If a diagnostic contained tests 1, 2, 3, and 4, this check would execute the initialization code followed by test 4, test 3, test 2, and then test 1. The types of QA errors that can occur are the same as those in the Normal Start check.

If the Run Backwards check succeeds, the overall error summary table is printed, a line is printed saying that the program passed Auto-QA, the Supervisor flags are restored to their previous settings, and the diagnostic is aborted.

G.2 START/QA

A new qualifier has been added to the START command. If the START command contains the /QA qualifier, QA will be performed on the currently loaded diagnostic program. If the /QA qualifier is present, the /PASSES, /SUBTEST, and the /TEST qualifiers are

ignored. The /SECTION qualifier may be used to run QA on a particular section in the program.

G.3 RUN/QA

The /QA qualifier has also been added to the RUN command. It functions exactly the same as the /QA qualifier on the START command.

G.4 QA Flags

There are five new Supervisor flags that will affect QA. However, only two of these are used in the current implementation.

The QAMULTIPLEPASS flag controls how many passes are performed in the Multiple Pass check. This flag may be set as follows:

```
DS> SET QAMULTIPLEPASS 10
DS> SET QAM 3
```

In addition, the current setting of the flag may be printed as follows:

```
DS> SHOW QAMULTIPLEPASS
DS> SHOW QAM
```

Note that the QAMULTIPLEPASS flag may be abbreviated to QAM. The initial (and default) setting for this flag is 10. That is, 10 passes of the diagnostic will be executed in the Multiple Pass check.

The QATESTLOOPS flag controls now many times each test is executed in the Loop on Test check. For example, if a diagnostic program contains three tests and QATESTLOOPS equals 2, this check will first execute the initialization code, then tests 1, 1, 2, 2, 3, and 3.

This flag may be SET and SHOWn in the same manner as the QAMULTIPLEPASS flag. This flag may be abbreviated to QAT. The initial (and default) setting for this flag is 100.

Also, the following command will set all the QA flags to their default settings:

```
DS> SET QADEFAULTS
```

QADEFAULTS may be abbreviated to QAD. To show the default settings (not the current settings) of the five QA flags, the following may be used:

```
DS> SHOW QADEFAULTS
```

G.5 Modifications Necessary For QA

Diagnostic programs wishing to undergo QA must call the $DS_ENDPASS macro in the initialization code. This is necessary for the internal Supervisor sequencing of QA checks. The branch macros discussed in the "Design Specification for Automatic Quality Assurance for Diagnostic Programs" need not be used in the diagnostics for this version of QA.

Because of the way the Supervisor works, the code executed in the diagnostic's initialization code when pass0 is true (in conjunction with the $DS_BPASS0 or $DS_BNPASS0 macros) will be done only once. It is done at the start of the Normal Start check. Also, the cleanup section will be done only once. It is done at the conclusion of the Normal Start check (before the Multiple Pass check is started).

Thus, the whole QA sequence of checks may be thought of as executing the diagnostic a number-of-passes times, with different things happening in different passes. That is, one pass is executed for the Normal Start check, then QAMULTIPLEPASS passes are executed in the Multiple Pass check, then one pass is executed in the Loop on Test check (with the tests executing more than once), and then one pass is executed for the Run Backwards check (with the tests being run in reverse order).

RELEASE NOTES FOR VAX-11 DIAGNOSTIC SUPERVISOR VERSION 6.7 03-May-1982

A. GENERAL ENCHANCEMENTS/NOTES

1. This release is almost identical to the Version 6.6 VDS which was released in the previous cycle. However, due to technical difficulties, particularly due to the support of VMS V2-style QIO interface in standalone, while linking VDS under V3 of VMS, it was not possible to release version 6.6 VDS for 11/780 and 11/750 processors.

   This release (6.7) includes all three processors; ENSAA (11/730), ECSAA (11/750), and ESSAA (11/780).

2. VMS V3a support

   Support of VMS V3a includes support for the new system directory structure, where [SYS0.SYSMAINT] replaces the old [SYSMAINT] directory. Earlier versions of VDS will not operate correctly with a 'rooted' SYSMAINT directory. This support requires DIAGBOOT.EXE V4, which was released with the previous release cycle.

   A side-effect of the support of rooted systems is that VDS now fully supports subdirectories in standalone mode.

   NOTE that while VDS 6.7 supports the directory structure of VMS V3a, it is linked under VMS V2.5, and so will run under VMS V2.5 or V3a.

3. New Device support

   VDS V6.7 includes support for the UDA-50 UNIBUS to SI disk adapter/controller, and for the RA- series disk drives which can attach to it.

B. COMMAND ENHANCEMENTS/ADDITIONS/FIXES

1. SELECT/DESELECT

   In version 6.5, the SELECT and DESELECT commands did not handle the new definitions of 'device uniqueness' correctly. If the device name specified was attached to more than one adapter, the commands would simply act upon the first such device found (unless the /Adapter qualifier was used). Since the SELECT command affects the order in which device names are searched, this often meant that it was impossible to DESELECT the device which had been SELECTed; yet no error message was given. Now, such a situation will result in an error message saying that the /Adapter qualifier must be used.

2. HELP

   In the process of major restructuring of the VDS command parser for version 6.5, a bug was inserted in the parsing of the HELP

command. Specifically, any command line which began with 'H' was taken as a HELP command; for example, a 'SHOW' command mis-typed as 'HSOW' was interpreted as if 'HELP SOW' had been typed. This has been fixed for VDS 6.6.

3. SHOW MEMORY

This new command displays the layout of VDS memory. In default mode, the start and end addresses of the diagnostic, VDS, and dynamic memory (used by VDS) are typed, as well as the physical memory size of the system, in both HEX and DECIMAL radix. There are several qualifiers to this command. Note that you can not use these qualifiers prior to the MEMORY keyword. E.g., 'SHOW MEMORY/ALL' but not 'SHOW/ALL MEMORY'.

a. /MAP : same as default mode

b. /DATA_STRUCTURE : shows internal VDS data structure addresses, including all stacks, page tables, SCB, and various simulated VMS data structures (PCB, PHB, etc.). knowing the addresses of these data structures can be usefull in debugging. Note that the memory layout in on-line mode is quite different than in standalone; in on-line mode, none of the aforementioned data structures are present within VDS memory space, and will not be displayed.

c. /BUFFER : Show available space for diagnostic buffers, both above and below VDS (this command is not meaningfull when no diagnostic is loaded). Note that since on-line mode allocates buffer space above VDS via $EXPREG as it is requested, /BUFFER on-line will not show space above VDS.

c. /ALL : Combine /Map, /Data_Structure, and /Buffer

4. DIRECTORY

The DIRECTORY command has been enhanced. Previously, it would accept as arguments only the device and directory parts of a filespec, and would take only one level of directory in standalone mode. Now, you can specify the filename, type, and version fields of the filespec; additionally, both the filename and type fields may include both "*" and "%" wildcards (with the same meaning as under VMS). Furthermore, subdirectory specification is now legal in standalone as well as on-line.

5. SUMMARY

The SUMMARY command has been enhanced. Whether or not the diagnostic program contains summary code, VDS will generate a header containing the name of the diagnostic and a summary of all HARD, SOFT, DEVICE, SYSTEM, and SUPERVISOR DETECTED errors which occurred during the run.

C. AUTOMATED DIAGNOSTIC QUALITY ASSURANCE

1. Introduction

These sections will explain what functionality I have added to the Automatic Quality Assurance enhancement to the Diagnostic Supervisor, and what problems I have fixed since the 6.5 version of the Supervisor. Note that when I speak of versions of QA or versions of the Diagnostic Supervisor, I am actually speaking of the same thing.

2. Additional Functionality

The following gives the two new QA checks that have been added to the 6.6 version:

a. Loop On Subtest check:
This check performs a loop on every subtest in the diagnostic. The number of loops is user-controlled via the QASUBTESTLOOPS Supervisor flag. The following is an example of how this check works:

Assumptions:
Diagnostic EXXXX contains two tests.
Test one has three subtests.
Test two has two subtests.
QASUBTESTLOOPS has been SET to 3.

Order of Execution (Test#.Subtest#):
1.1
1.1
1.1

1.1
1.2
1.2
1.2

1.1
1.2
1.3

2.1
2.1
2.1

2.1
2.2
2.2
2.2

2.1
2.2
End of Pass

In the above, the blank lines represent places where QA

internally aborts the diagnostic and restarts it so as to start looping on the next subtest. The ENDPASS routine is only executed at the very end of the check. However, the initialization code and the cleanup code are both executed once for each of the above groupings.

b. Error Phase One check:
This QA check forces as many error reports as possible to be printed. This is a way of insuring that the parameters passed to the error routines are correctly coded, as well as allowing the user to check the format of the error messages. The following lists some points that must be considered when writing a diagnostic that will be QA'ed using Auto-QA:

i. Any error call that was not forced (i.e., was not preceeded by a branch macro in which QA forced the branch to change sense) will be treated as a QA error, resulting in termination of Auto-QA.

ii. No two branch macros should occur in sequence without an intervening error macro call. That is, the sequence should always be one branch macro followed by one error macro call.

iii. No branch macros should occur in a subroutine. Branch macros in subroutines may cause QA to go into an infinite loop and print error reports ad infinitum! This may be fixed in a later version of QA.

iv. The branch macros for use in MACRO diagnostic modules are listed below. For an explanation of the parameters, see Revision 1.1 of the "Functional Specification for Automatic Quality Assurance for Diagnostic Programs" memo. Contact Jack Stansbury (TW/F18) for a copy of this memo.

```
$DS_BLSS        ADR, NUM
$DS_BLSSU       ADR, NUM
$DS_BLEQ        ADR, NUM
$DS_BLEQU       ADR, NUM
$DS_BEQL        ADR, NUM
$DS_BEQLU       ADR, NUM
$DS_BGEQ        ADR, NUM
$DS_BGEQU       ADR, NUM
$DS_BGTR        ADR, NUM
$DS_BGTRU       ADR, NUM
$DS_BGTRU       ADR, NUM
$DS_BNEQ        ADR, NUM
$DS_BNEQU       ADR, NUM
$DS_BVS         ADR, NUM
$DS_BVC         ADR, NUM
$DS_BCS         ADR, NUM
$DS_BCC         ADR, NUM
$DS_BBS         POS, BASE, ADR, NUM

$DS_BLBC        SRC, ADR, NUM
$DS_BERROR      ADR, NUM
$DS_BWERROR     ADR, NUM
```

v. The branch macros for use in BLISS diagnostic modules are as follows (note that the BCS, BCC, BVS, and BVC branch macros are not implementable in BLISS):

```
$DS_BLSS    (VAL, NUM)
$DS_BLSSU   (VAL, NUM)
$DS_BLEQ    (VAL, NUM)
$DS_BLEQU   (VAL, NUM)
$DS_BEQL    (VAL, NUM)
$DS_BEQLU   (VAL, NUM)
$DS_BGEQ    (VAL, NUM)
$DS_BGEQU   (VAL, NUM)
$DS_BGTR    (VAL, NUM)
$DS_BGTRU   (VAL, NUM)
$DS_BGTRU   (VAL, NUM)
$DS_BNEQ    (VAL, NUM)
$DS_BNEQU   (VAL, NUM)
$DS_BBS     (POS, BASE, NUM)
$DS_BBC     (POS, BASE, NUM)
$DS_BBSS    (POS, BASE, NUM)
$DS_BBSC    (POS, BASE, NUM)
$DS_BBCS    (POS, BASE, NUM)
$DS_BBCC    (POS, BASE, NUM)
$DS_BBCCI   (POS, BASE, NUM)
$DS_BBSSI   (POS, BASE, NUM)
$DS_BLBS    (SRC, NUM)
$DS_BLBC    (SRC, NUM)
$DS_BERROR  (VAL, NUM)
$DS_BWERROR (VAL, NUM)
```

After all the errors are forced, a table is printed that summarizes the error numbers. This is the Forced-Error Summary table. This table looks like the following:

Summary of Forced-Errors

Test X1	Subtest Y1
aaaaa-bbbb	ccccc-dddd ...
aaaaa-nnnn	...

Test X2	Subtest Y2

```
AAAAA-BBBB CCCCC-DDDD EEEEE-FFFF GGGGG-HHHH ...
MMMMM-NNNN OOOOO-PPPP QQQQQ-RRRR ...
...
```

The error numbers are printed in a test/subtest order, with the error numbers sorted within each test/subtest.

The Xi and Yi are the test and subtest numbers, respectively. The 'aaaa', 'cccc', ... 'AAAA', 'CCCC', etc. are the error numbers that are passed to the $DS_ERRxxxx macro.

The 'bbbb', 'dddd', ... 'BBBB', 'DDDD', etc. are the number of times that error was forced. This number should be one except in those cases where the same error number is used more than once in one subtest.

If the diagnostic runs on a subset of the total number of tests in the DEFAULT section (by using the /TEST qualifier), the Overall Error Summary table will not be printed.

However, if the /TEST qualifier is not used, the Overall Error Summary table will be printed. This table gives the number of errors that occurred in each QA check. For the 6.6 version of the Supervisor, these numbers should be either all zeroes (in which case a line is printed saying the program passed Auto-QA), or else there will be at most one error (since Auto-QA is aborted upon detection of a single QA error).

3. Auto-QA Problems in the 6.5 Version

The following is a list of problems with QA that were discovered in the 6.5 version of the Supervisor:

a. The Halt-On-Error flag was not cleared before starting QA. I had meant to clear all the Supervisor flags when QA started, and then restore them when QA ended. However, I forgot this one flag. Although it probably will not cause any problems in the 6.5 version, it would have caused problems in this new version.

b. If a previously-started diagnostic is running, a Control-C is typed, and then a CONTINUE Supervisor command is executed, Auto-QA will start behaving strangely (it will set the number of passes to 0, and start executing forever).

c. The cleanup code in the diagnostic was executed at the end of the first QA check, the Normal Start check. After executing the cleanup code, QA caused the diagnostic to continue running by starting the Multiple Pass check. That is, the /QA qualifier on the START or RUN commands cause the following to happen:

   1. The diagnostic is started and executes one pass.

This means it executes the initialization code (doing the pass-zero things, such as allocating buffers and assigning channels), then executes all the tests in the appropriate section (the DEFAULT section by default).

ii. Then, after executing the last test in that section, the Supervisor calls the initialization code again. This time, the pass-zero things will not be done and the ENDPASS routine will be called.

iii. The ENDPASS routine calls the diagnostic's cleanup code (where the buffers are usually deallocated and channels deassigned).

iv. Normally at this point (i.e., when NOT under control of QA), the Supervisor would return to command mode. However, QA will cause the ENDPASS routine to set the number of passes to QAMULTIPLEPASS (settable via a "SET QAMULTIPLEPASS" DS command) and start the Multiple Pass QA check.

v. This causes test one to execute again. Note that the initialization code is NOT executed in between the Normal Start check and Multiple Pass check. Thus, the buffers that were deallocated at the end of the Normal Start check (in the cleanup code) are no longer available to the diagnostic in the Multiple Pass check. This was causing several diagnostics (including the Cluster Exerciser) to fail.

d. The branch macros (i.e., $DS_BERROR, $DS_BLBS, $DS_BBS, $DS_BNEQ, etc.) will destroy the contents of R0. This happens because the branch macros expand into a Supervisor service routine, which is executed with a CALLS instruction. Since R0 is never saved across CALL instructions, the contents can not be guaranteed upon return from this routine.

e. The register values that are printed out when a QA error is detected are incomplete. That is, at most three of the registers are correct, with the others having a default value of zero. This led to some confusion.

f. The /TEST qualifier was ignored on the START or RUN commands when used in conjunction with the /QA qualifier.

g. The /SECTION qualifier did not work properly when used in conjunction with the /QA qualifier. The DEFAULT section is the only section that can be run when using the /QA qualifier.

4. Fixes to the Above Problems

The following describes the status of the above problems:

a. The HALT flag is now cleared when QA is running. As with the other Supervisor flags (e.g., IE1, IE2, IE3, TRACE, BELL, etc.), it is restored to its previous state (i.e., to the same setting it had before the START or RUN command was executed) after QA finishes.

b. A Control-C will now cause the diagnostic currently being QA'ed to be aborted only if Control-C has NOT been disabled by the diagnostic. That is, if the diagnostic has disabled C's, C's will be ignored when running under QA. If the diagnostic has not disabled C's, (they are enabled by default), the Supervisor will gain control (before the diagnostic's Control-C handler) and will abort the diagnostic. Note that a CONTINUE Supervisor command in this context will not work.

c. The way the QA check routines execute the diagnostic has been fundamentally changed. Whereas before the sequence of checks could be thought of as executing a variable number of passes of the diagnostic, the sequence is now like STARTing the diagnostic a fixed number of times (the number of times depends on the number of QA checks).

For example, ASSUMING (note that even though there is none, this has been suggested as an enhancement) there was a new qualifier on the START (and RUN) command that would allow one to select which particular QA check routine to execute (such as /QA=NORMAL_START to execute ONLY the Normal Start QA check on the diagnostic), then the sequence of checks can now be thought of as being:

```
DS> START/QA=NORMAL_START
DS> START/QA=MULTIPLE_PASS
DS> START/QA=LOOP_ON_TEST
DS> START/QA=LOOP_ON_SUBTEST
DS> START/QA=RUN_BACKWARDS
DS> START/QA=ERROR_PHASE_ONE
```

That is, the diagnostic program is reSTARTed at the beginning of each QA check and executes as though a normal START Supervisor command had been executed. This implies that the initialization code is always done at the beginning of each check routine, then all the tests execute (a varying number of times depending on which QA check is executing), then the ENDPASS routine is executed causing the cleanup code to execute, and then the next QA check routine performs the same way. This new implementation should alleviate the deallocation problems encountered by several people.

d. The implementation of the branch macros has changed somewhat. Some diagnostic engineers felt that the $DS_BERROR and $DS_BNERROR macros should NOT alter the contents of R0 both when QA is not running, and when QA is running but not forcing errors (as happens in the Error Phase One QA check). In this version of the Supervisor and of the DIAG library, the $DS_BERROR and $DS_BNERROR macros will alter the contents of R0 only

when QA is running and forcing errors.

For branch macros other than $DS_BERROR and $DS_BNERROR, the contents of R0 may change across the branch macro call. The main reason an exception was made in the case of the above two macros is that they existed prior to the QA enhancement and did not alter the contents of R0. Therefore, to be compatible with old diagnostics, it was felt that this should not change. However, with the new branch macros, R0 will change only in the low bit position (i.e., it may change from a one to a zero, or vice-versa). Note that this bit may change even when the /QA qualifier is not being used (i.e., in normal running of the diagnostic).

e. The register values printed out when a QA error is detected are now correct. The values printed are the values at the time of the call to the Supervisor Service routine that produced the QA error (e.g., a $DS_ERRHARD call).

f. The /TEST qualifier is no longer ignored when used in conjunction with the /QA qualifier. This allows one to run QA on a particular test in a diagnostic, or on a range of tests. However, if the /TEST qualifier is used, the Overall Error Summary table is not printed (see later section).

g. The /SECTION qualifier is still essentially ignored. This will be fixed in the next version of the Supervisor.

D. DIAGBOOT (DIAGNOSTIC SECONDARY BOOTSTRAP PROGRAM)

(DIAGBOOT has not changed from release 6.6 to 6.7 of VDS; this section is included for the convenience of those who have not seen the 6.6 release notes).

DIAGBOOT is loaded by VMB when a BOOT command is issued with register 5 bit 4 set. DIAGBOOT will sense the type of processor (11/780, 11/750, or 11/730) and load the appropriate VDS image (ESSAA, ECSAA, or ENSAA respectively). This new version of DIAGBOOT (version 4) supports the new VMS rooted systems (the old [SYSMAINT] becomes [SYS0.SYSMAINT], or [SYS1.SYSMAINT], etc.). The high nibble (bits 28 to 31) of R5 at boot time represent the hex digit which should be converted to ASCII and appended to the root directory name 'SYS'; this allows system root directories of 'SYS0' to 'SYSF' to co-exist on the same disk pack.

This new version of DIAGBOOT also allows the VDS image being booted to be non-contiguous. With previous versions of DIAGBOOT, VDS had to be contiguous.

RELEASE NOTES FOR
VAX-11 DIAGNOSTIC SUPERVISOR
VERSION 6.8
6-Jul-1982

A. GENERAL ENCHANCEMENTS

1. ATTACH enforces device naming conventions

An additional Ptable descriptor statement ($DS_$NAME; see VAX-11 Diagnostic Design Guide, chapter 17 for information) allows VDS to verify the names given to devices when they are attached. For example, when an RK07 is ATTACHed, it must have a name of the generic format 'ggan', where 'gg' is the device generic prefix, 'DM', 'a' is the controller letter of the RK611, and 'n' is the unit number. Previously, VDS imposed no constraints on device names other than on whether a unit number was allowed, and on the magnitude of the unit number if allowed.

Because this is new functionality, and some old SCRIPTS or even diagnostics may not function under these new constraints (e.g., scripts which ATTACH an RK07 as 'DM0'), new commands have been implemented which will enable and disable this functionality under operator control. The commands are:

- SET ENFORCE : This command enables enforcement of device name enforcement. It is the default condition when VDS starts, EXCEPT when running under APT.

- CLEAR ENFORCE : This command disables enforcement of device name enforcment. It will cause VDS to behave as it did prior to this enhancement. CLEAR ENFORCE is the default condition when VDS is run under control of APT.

****NOTE****
These commands are intended only for EMERGENCY use. You should fix your script files and/or diagnostic programs immediately to conform to the device naming conventions.

2. AUTOSIZER (EVSBA) changes

The autosizer (EVSBA V1.4) has been modified to generate the correct names for V6.8 of the Diagnostic Supervisor. The entire attach command line generated for each device is described in a separated document.

3. $DS_ERRPREP_x [num], [unit], [msgadr], [prlink], [p1--6]

A new error message facility has been added to the Supervisor

for detecting device preparation errors. You should use this macro after detecting a device preparation error (e.g. disk not spinning) instead of another error message facility. The parameter list is the same as for the other error macros and is fully described in section 8.7 of the Vax-11 Diagnostic Design Guide (EK-1VAXD-TM-002).

B. GENERAL BUG FIXES

1. KERNEL STACK NOT VALID ABORTS

Previously, VDS allocated only 3 pages for KERNEL mode stack. In certain commands, notably a directory of an ODS stuctured disk (standalone only, with MM ON), these 3 pages could be overflowed, resulting in a KERNEL STACK NOT VALID ABORT, due to the page below the kernel stack being marked 'no access' to catch stack overflows. To minimize the chances of this sort of behavior, the kernel stack has been expanded to 10 pages for V6.8. This problem can not occur in on-line mode (under VMS).

2. TM03/TE16/TU45/TU77

The problem with not being able to access magtapes on this controller through the Supervisor has been solved in this released.

3. MACHINE CHECK LOGOUT

The machine check logout for the 11/780 (ESSAA) has been changed to show the error summary register in addition to the other parameters.

C. NOTES

1. TM78 SUPPORT

VDS theoretically supports MAGTAPE devices as file load devices. Currently, the only Magtape devices supported are TM03 and TS11 controllers. This release includes the beginnings of TM78 (TU78 drive) support: however, due to a lack of standalone hardware, it is not debugged or supported. This note is just to warn those who may try a file command (DIRECTORY, HELP, LOAD, RUN) from a TM78 magtape, or who look at the VDS map listing and see 'TFBTDRIVR' (which is the VDS TM78 readonly driver) that the TM78 code is undebugged and probably will not work as-is. However, TM78 support will be completed as soon as possible, and documented in a future release.

2. INTERRUPT STACK

The INTERRUPT stack size has be increased 4 pages so the priviledge exerciser can print out errors without failing.

3. CUSTOMER RUNNABLE DIAGNOSTICS (CRD)

The Supervisor has been enhanced to support CRD AUTO TEST on the 11/730 machine. For more information on CRD, see the "Nebula Customer Runnable Diagnostics Functional Specification" DTM-82-001-01, document.

RELEASE NOTES FOR VAX-11 DIAGNOSTIC SUPERVISOR VERSION 6.9 8-Nov-1982

1.0 BUG FIXES

- The following sequence of commands caused a "?? Translation not valid Fault ..." :

```
DS> SET MM ON
DS> ATTACH ...
```

  This occurred only in standalone mode, and only if a program had not been previously loaded with a supervisor LOAD command.

- A "^Z", typed at the console terminal in stand-alone mode, echoed garbage as a non-printing character. It has been fixed so that it now imitates the supervisor EXIT command, and returns control to the console program.

- The following error message appears when any file services (such as LOAD, RUN, DIRECTORY, HELP, and script files) are attempted with an RL11/RL02:

  %RMS-F-DEV, bad device, or inappropriate device type (R0=000184C4)

  This is a bug only in version 6.8 in standalone mode, and is fixed in version 6.9.

- Also, only in version 6.8 and only for the 11/750, there is a bug which prevents the supervisor from loading large files from the console TU58 tape cartridge. Some small files could be loaded. Typically, the tape cartridge indicator light would remain lit for an excessively long time, and eventually the supervisor would respond with an error message. This is fixed in version 6.9.

- New versions of VMS which modify the system service transfer vector table experienced a problem running the supervisor in on-line mode. This occurred because the supervisor copied three pages of system service vectors for its own use, but the transfer vectors had been modified to branch into a fourth page. In order to accomodate other possible modifications to the VMS system service transfer vectors, the supervisor's transfer table was modified to jump directly to the actual VMS system service transfer vector table.

2.0 ENHANCEMENTS

- Support for the TM78/TU78 magnetic tape device as a file load device is now functional. This means that commands such as DIRECTORY, HELP, LOAD, and RUN, will now work when the TU78 is ATTACHed and a SET LOAD command has been executed.

- The SHOW MEMORY/BUFFER command has been enhanced to show the amount of buffer space in use by the diagnostic. The command displays the amounts in use in P0, P1, and S0 space (the number of pages in use). Previously, only the available buffer space was displayed. The SHOW MEMORY/ALL also displays this information.

- CUSTOMER RUNNABLE DIAGNOSTICS (CRD): VAX-11/730 MENU TEST

  The VAX Diagnostic Supervisor now supports VAX-11/730 MENU TEST (CRD MENU) as part of the CRD Package. CRD MENU is an off-line Menu-driven test feature of CRD. The purpose of CRD MENU is to provide the customer, or inexperienced operator, stand-alone VAX Diagnostic test capability for the VAX-11/730 'base' system package and, in particular, for VAX-11/730 Add-on options. CRD MENU, therefore, represents a complementary test package to VAX-11/730 AUTO TEST (see DTM-82-001-01 Nebula CRD Auto Test Functional Specification).

  CRD MENU, when invoked, will automatically determine CRD MENU supported hardware on the system and satisfy the necessary software requirements required for executing VAX Diagnostics. Through the Menu interface, the operator may select and test one supported hardware unit for test, or with the 'Test All' mode feature, select and test all supported system hardware. CRD MENU, therefore, provides full functional verification and fault isolation to the subsystem level of the system.

  CRD MENU is invoked by VAX-11/730 Console Command (typing 'T/M' to console prompt), at the successful completion of VAX-11/730 AUTO TEST (invoked by typing 'T' to console prompt), or from VAX Diagnostic Supervisor Command Level (typing 'CRD' to VDS CLI command prompt). However, the 'CRD' Supervisor command is not supported for use in Supervisor command files.

  Four new Supervisor commands have been added for CRD MENU Test. The commands are as follows:

  ```
  SET CRD/TRACE
  CLEAR CRD/TRACE
  SHOW CRD
  CRD
  ```

  The functions of these commands are explained in the ENSAB.DOC file.

For additional information:

- see ENSAB.DOC
- see the Functional Specification for VAX-11/730 MENU TEST
- Type "HELP ENSAB MENU" to VDS CLI Command prompt (this requires that the ENSAB.HLP file be on the load device).

3.0 MISCELLANEOUS

- A bug in the $D1_ERR_L MACRO in DIAG, which caused an invalid conditional directive, has been fixed.

4.0 KNOWN BUGS AND DEFICIENCIES

- The following commands will cause an error message if a comment follows the command:

```
SET ENFORCE
CLEAR ENFORCE
SET CRD/TRACE
CLEAR CRD/TRACE
SHOW CRD
CRD
```

For example,

```
DS> SET ENFORCE             ! Comment
?? Illegal command
   \SET ENFORCE             ! C\
```

All of the above commands except the 'CRD' command will still perform their correct function even though the Supervisor responds with "?? Illegal command". NOTE: the 'CRD' command will FAIL if the command is followed by a comment on the same line.

F 4

RELEASE NOTES FOR VAX-11 DIAGNOSTIC SUPERVISOR VERSION 6.10 3-Jan-1982

1.0 BUG FIXES

- The 6.9 VDS bug concerning comments on the following Supervisor commands has been fixed. All of the following commands now accept comments after the command:
  - SET ENFORCE
  - CLEAR ENFORCE
  - SET CRD/TRACE
  - CLEAR CRD/TRACE
  - SHOW CRD
  - CRD

2.0 ENHANCEMENTS

- Support for the TM80 magnetic tape device as a file load device is now functional. This means that commands such as DIRECTORY, HELP, LOAD, and RUN, will now work when the TU80 is ATTACHed and a SET LOAD command has been executed.

- A new supervisor service call, which loads the COMET PCS microcode and patch bits, has been added. The service is called by a supervisor macro, $DS_LOADPCS_x ($DS_LOADPCS_DEF, $DS_LOADPCS_G, $DS_LOADPCS_L, and $DS_LOADPCS_S for MACRO and $DS_LOADPCS for BLISS), with no arguments. The service returns DS$_NORMAL if the service is completed successfully, and DS$_NOPCS if PCS is not available on this CPU. Currently, the only diagnostic program which uses this call is ECKAX. This release does not contain PCS microcode which affects any instructions. It merely restores the PCS to a known state. If the CPU attempts to execute any of the PCS microcode, an error message will be printed out.

3.0 MISCELLANEOUS

-

4.0 KNOWN BUGS AND DEFICIENCIES

0

RELEASE NOTES FOR
VAX-11 DIAGNOSTIC SUPERVISOR
VERSION 6.11
23-May-1983

1.0 BUG FIXES

- Implementation of Control-Z recognition in standalone mode was done incorrectly and has been removed, although no symptoms have been discovered.

2.0 ENHANCEMENTS

1. VDS 6.11 supports booting and file loading from HSC50 on CI780.

3.0 MISCELLANEOUS

2. The device name for booting from the RP07 disk will now be DRan and not DBan.

3. The driver for the TM78/TU78 was changed to have a longer delay between accesses of the ATTENTION register during the wait for command completion to prevent spurious operations caused by false signals. The driver was enhanced to work with tapes written at 6250 b.p.i and be usable on drives other that number 0.

- 0

4.0 KNOWN BUGS AND DEFICIENCIES

- 0

RELEASE NOTES FOR
VAX-11 DIAGNOSTIC SUPERVISOR
VERSION 6.12
21-Jul-1983

1.0 NEW FEATURES

- The SET WIDTH command has been changed to work in online mode. The default is the same as for standalone mode, 80 characters.

- The SET PAGE command has been added to freeze terminal output after a specified number of lines. The user is then prompted for more output. The default value is zero, which indicates that no paging will be done. In order to determine a maximum value for a video terminal such that no terminal output will be lost, subtract 2 from the number of lines capable of being displayed at one time by the terminal. Two is the number of lines taken by the prompt message. Thus, for a VT100 with a 24 line screen, SET PAGE 22, will print the maximum amount of lines without any being lost.

- A change has been made so that a person creating a script can force the answer to a prompting question to be fetched from the user terminal instead of from the script. If, in the script, a prompting message is followed by "" instead of the answer to the prompt, then the vds will print that prompt on the terminal and wait for a response to be typed. then the vds will continue executing the script. full documentation on this feature will be available in the next version of the vax-11 diagnostic design guide.

- the rc11 p-table descriptor has been added, so that aztec is now supported with p-table descriptors for the rc11, rc25, and rcf25.

- a new vds service has been added, called $dsGetterm. this service, "get terminal characteristics", can be used in both standalone and user mode to obtain characteristics about the user terminal. you can determine the terminal type, whether it is a video or hardcopy terminal, other information. full documentation on this feature will be available in the next version of the vax-11 diagnostic design guide.

2.0 BUG FIXES

- A problem with ECKAX hanging has been fixed. The CLRVEC routine was changed to reset the clock vector before resetting the clock. This compensates for the TOK hardware bug on 11/750s, which caused interrupts once in a blue moon when resetting the clock.

- $DSPRINT macros now return an error status. SS$NORMAL, SS$BUFFEROVF, or SS$BADPARAM will be returned.

- $DSINLOOP will return DS$NORMAL or DS$ERROR, instead of just setting or clear the low bit of R0.

3.0 MISCELLANEOUS

- LCN Low Cost Nebula will be supported with ENSAA diagnostic Supervisor.

RELEASE NOTES FOR VAX-11 DIAGNOSTIC SUPERVISOR VERSION 6.13 21-Nov-1983

1.0 NEW FEATURES

o

This is the first Diagnostic Supervisor to be linked under version 3 of VMS. Therefore it will not function correctly under those systems running version 2 or earlier versions of VMS.

o

The method of attaching the load path to the CI network has been modified to allow access to a user specified disk on the HSC50 controller. An example of the attach command lines for the 11/780 follows:

```
DS> ATTACH CI780 HUB PAA0 14 5 4
DS> ATTACH CI_NODE PAA0 CIA10 HSC50 10
DS> DISK CIA10 HSC50$DUA1
```

Please note the addition an extra attach command line for DISK and the new form of the generic name. The name must be of the form 'name$DUannn' where 'name' is any alphanumeric string 1 to 6 characters long, and the '$DU' is required. The controller, 'a', is usually 'A' and 'nnn' is the disk unit number.

o A "SET MEMORY n" command has been added which allows the operator to change the amount of total physical memory available to the supervisor and diagnostic programs. This feature is useful when it is desired to verify that a diagnostic program and the supervisor will run in a smaller amount of memory than is actually available on the system.

The unit of measurement for "n" is pages. The value of "n" must be greater than or equal to zero, but less than the last value specified for total available physical memory. Total available physical memory may be reset to the actual available physical memory by using a value of zero for "n". A value greater than the actual available physical memory will be accepted but not used.

The command will not be accepted in user mode. Also note that any devices attached or selected will be deselected and deattached after performing the command.

o An "INITPCS" command has been added. When this command is executed, the supervisor searches for the PCS750.BIN file on the console TU58. If it is found, the supervisor onboard image of the PCS750.BIN is

overwritten with the image found on the TU58. Otherwise, the supervisor onboard image remains the same. Then, the PCS is reloaded with the current PCS image.

This command will be useful when the supervisor being run does not contain the latest PCS750.BIN file, but the file is available on the console TU58. The command is not accepted when running the supervisor under VMS, and will only be accepted when running on an 11/750.

Also, this supervisor contains version CMT098 of PCS microcode patches.

2.0 BUG FIXES

- A bug in the $DS_EXIT TEST macro, which caused an "[aborted]" message to be printed if TRACE was set and the low bit in R0 was clear, has been fixed. Now, the "[aborted]" message will only appear if the program does a $DS_ABORT TEST

3.0 MISCELLANEOUS

RELEASE NOTES FOR VAX-11 DIAGNOSTIC SUPERVISOR VERSION 6.14 20-Feb-1984

1 NEW FEATURES

- New device support is provided for DMZ32.

2 BUG FIXES

- Several supervisor BOOTDRIVRs use the TODR to perform a timeout function. For the 11/750, the TODR remains at zero if the battery backup has failed, and the system has been powered off. Thus, the TODR in this case was not able to perform the timeout function correctly. However, the BOOTDRIVRs were written so that the code would always appear to succeed. This has been fixed by writing a 1 into the TODR (which starts the clock ticking) if the battery backup has failed and the system was powered down. This may fix some of the 'unkown error' problems with supervisor file services for 11/750s.

- The problem of terminal output from a user's control-C handler being suppressed has been fixed. This bug occurred only in standalone mode.

- When a diagnostic is aborted, the supervisor attempts to print out a user PC. When run under VMS, sometimes a PC in VMS system space was printed. This has been fixed.

3 MISCELLANEOUS

- The SET MEMORY command has been enhanced so that ptables for the console load device and the boot path devices are saved. Previously, all ptables were lost.

- The format of supervisor messages which inform the user that an interrupt, trap, or exception has occurred, has been changed to state that the interrupt, exception or trap occurred through an SCB vector rather than just a vector. For example,

?? Reserved/privileged instruction Fault through SCB
vector: 10(X)

instead of,

?? Reserved/privileged instruction Fault through
vector: 10(X)

RELEASE NOTES FOR
VAX-11 DIAGNOSTIC SUPERVISOR
VERSION 7.0
18-Jul-1984

1 NEW FEATURES

o VMS V4 support

1. Long file name support.

Long filename support has been added to this version of VDS. A full file specification will have the capability for the filename and filetype each to have up to 39 characters maximum. The version number can have up to 5 characters. The directory names can have up to 39 characters and up to 7 nested sub-directories, each with up to 39 characters. The device names can have up to 15 characters and overall the full file specification is not to exceed 252 characters including punctuation.

EXAMPLE: DEVICE:[DIRECTORY]FILENAME.TYPE;VERSION
15 39.39.etc 39 39 5

2. Long device names.

Support code has been added to allow for device names up to 15 characters. VDS will scan 'device name' line for the long device name format. If found VDS will dynamically add device name buffer space to the Ptable,otherwise device names of the format 'ggan' will be handled as before. In both cases, ,the quadword descriptor ,HP$Q_DEVICE, will contain the length and string address of the device name and HP$T_DEVICE will contain the device name with the format of 'ggan'. The new device name format will be as follows: 'name$ggan',the total combination of which must not exceed 15 characters.

3. DIRECTORY/WIDE

In order to display long filenames, the DIRECTORY command now has a /WIDE switch, which causes one filename per line to be printed. A DIRECTORY command without the /WIDE switch will display filenames in four 20-character columns, but for filenames longer than 20 characters, truncation will occur.

4. The value of the symbols IPL$_TIMER and $IPL_SYNCH is changed from 7 to 8 in VMS V4 library LIB. The supervisor, however, will continue to use the old value (7), because of possible conflicts between QIO services

and timer services. In order that diagnostics are encouraged to use the old value, the $IPLDEF macro has been included in the DIAG libraries.

5. This supervisor is not supported on versions of VMS prior to version 4.

2 BUG FIXES

- The $DS_CI_NODE ptable has been changed so that a response of KL10 to the Node_type question produces a value of 6 and a response of CINT a value of 7.

- Some internal supervisor errors of the form:

    ?? Software detected error in ...

  were causing the supervisor to hang in the middle of printing out the rest of this message. This has been fixed.

3 MISCELLANEOUS

- The supervisor now displays a legal statement at boot time regarding the right to use of the diagnostic supervisor and diagnostic programs.

  Two new VDS services, $DS_MOUNT and $DS_DISMOUNT, have been added.

- As of VMS Version 4, you cannot issue a VMS MOUNT command before running the VDS. If you do, and if the device's p-table indicates that the device should be allocated, then the VDS SELECT command will fail. This failure occurs because the SELECT command will try to allocate the device, but you cannot allocate a device that has already been mounted (in VMS V3 you could, if the device had been mounted by you and not someone else).

  Any diagnostic programs that require a device to be allocated AND mounted before it is tested will not work with this release. We know of only one such diagnostic, EVRMD. We are in the process of correcting the problem. The correction will be in a future release.

- When the supervisor is run in online mode (under VMS), the default load path has been changed to be equivalent to SYS$SYSROOT:[SYSMAINT]. Previously, a bug in the supervisor caused the default load device to be the translated value of SYS$DISK from the process name table rather than from the system name table. Normally, SYS$SYSROOT:[SYSMAINT] is the equivalent of SYS$MAINTENANCE, and the supervisor will be changed in some future release to fully translate SYS$MAINTENANCE.

RELEASE NOTES FOR VAX-11 DIAGNOSTIC SUPERVISOR VERSION 7.1 18-Jul-1984

1 NEW FEATURES

- A new VDS macro has been added to return the size of physical memory, expressed in number of pages. The macro is called DS$MEMSIZE and it accepts one argument, the address of a storage location that will receive the memory size.

- A new VDS command has been added which will print the number and name of the tests in the currently loaded diagnostic program. The command is called SHOW TESTS.

- A new qualifiers has been added to the SELECT command: /NOALLOCATE. When this qualifier is used the device selected will not be allocated to the VDS user. This parameter should be used when selecting a device that is already allocated to another user. Also, the SHOW DEVICES and SHOW SELECT will display the allocation status of the devices for your current process.

- The TU81 magtape is now fully supported as a load device. You can now do operation with tapes at 1600 bpi and 6250 bpi.

- A new naming convention which allows name of the form $m$ggan is now permitted for generic names when you do ATTACH commands. The '$' signs are required and the allocation class 'm' must be a decimal number between 1 and 255. The 'gg' is the normal name with 'a' the controller and 'n' the unit number if required.

2 BUG FIXES

o

A flaw in the operation of the EXAMINE command has been corrected. The fix involved incorrect parsing of an EXAMINE of storage locations 'A' and 'F', which were being confused with the registers AP and FP. The EXAMINE command now works as it should.

o

If the TODR contained a value less than ^X10000000, the supervisor was not recalibrating its software clock from the TODR. This has been fixed by writing the value ^X10000000 to the TODR if the TODR contained less than ^X10000000. Thus, the supervisor will set the TODR at supervisor boot time to ^X10000000 if the TODR contained less than ^X10000000 (^X10000000 is the bias added to the current time of day so that powerfails where the battery back-up also fails can be detected.)

This bug may have caused the supervisor's software time count to become inaccurate when diagnostic programs, which used many $DS_WAITUS or $HIBER calls, were run when the battery back-up had failed.

o Corrected memory data and write bus timeout interrupts were not being forced to use the interrupt stack for the 11/750. This release forces those interrupts to use the interrupt stack. No known symptom had been reported.

o

The command SET PROMPT works properly now as it had not in the past.

3 KNOWN BUGS AND DEFICIENCIES

o

If the 11/750 diagnostic supervisor is booted from a non-console device (a disk), the supervisor is started with cache turned off. This will cause some diagnostic programs, which use supervisor timing services (such as $DS_WAITUS or $DS_WAITMS), to fail in bizarre ways. Therefore, we recommend that you either boot the supervisor from the console TU58, or boot from a disk and then turn on cache with the following supervisor command:

```
DS> DEPOSIT P2S 0
```

This will be fixed in the next release of the diagnostic supervisor.

RELEASE NOTES FOR
VAX-11 DIAGNOSTIC SUPERVISOR
VERSION 8.0
Jan. 7, 1985

1 ANNOUNCING A NEW SUPERVISOR, EDSAA, TO SUPPORT THE VAX-8600!

1.1 New Features Include:

o Dual SBI system, SBIA0 and SBIA1, that must be attached to the hub, which is an ABUS, for the 8600. MBA, UBA and CI adapters are then attached to either SBIA0(SI0), or SBIA1(SI1).

For example, ATTACH SBIA HUB SI0
ATTACH SBIA HUB SI1

Then any adapter is attached to either SI0 or SI1.

With a dual SBI configuration on the 8600, it is possible to have a maximum of 8 Unibus's, 4 on each SBI. To accomodate this situation, changes were made to the DW780 Ptable macro. The number of units was changed to accept 8 maximum. Since 3 bits are needed to specify attaching of DW0-DW7, and the DW780 macro only stores the lower two bits of _DRIVE into the _DVA field, the Unibus address space translates as follows: (using a CSR of 760000)

Unibus 0 and 4 = 2013E000

Unibus 1 and 5 = 2017E000

Unibus 2 and 6 = 201BE000

Unibus 3 and 7 = 201FE000

The recommended way of attaching 8 DW780'S:

for SBIA 0, DW0, DW1, DW2, or DW3.

for SBIA 1, DW4, DW5, DW6, or DW7.

WARNING: DW0 and DW4 should not be attached to the same SBIA since they translate to the same Unibus address space. Likewise for DW1 and 5, DW2 and 6, and DW3 and 7.

o Support for the Environmental Monitoring Module, EMM, is included in this supervisor. If any alerts are received from the EMM module from a power supply, temperature sensor, or air blower, the VDS will report a message on the console and

then resume operation.

- This supervisor also supports control from a remote terminal. To make a remote connection, the terminal control switch of the CPU must be set to REMOTE, and a modem must be connected to the rear async-panel port. Then the user can dial-up the cpu and remote connection will occur. You may dial up at any time, either before booting the supervisor, or while the supervisor is up and running.

  Note that terminal input from local or remote consoles will be echoed on both! Thus, if you are using the remote terminal, you can send messages to a user at the local terminal, and vice versa, by prefixing the message with a "!", which indicates a comment line to the supervisor's command parser.

  Also note that command input from both console terminals is not separated by the diagnostic supervisor, so if both users type a command at the same time, the diagnostic supervisor will see a garbled command and report that an illegal command was typed.

1.2 New Features

1. The "delete" key for video console terminals will now do a backspace, space, backspace sequence, which results in erasure of the previous character.

1.3 Bug Fixes

1. Previously, the DIRECTORY command returned "Total of 0 files." when used on the console storage device and a filename or wildcarded filename was specified as an argument. This has been partially fixed, such that if you specify a filename * extension, or a wildcard filename * extension, or a filename * wildcard extension, or some other combination, the desired result will be correct. Note that not all combinations of wildcarding work, and that this is only a problem for the console storage device.

2. Previously, when the 11/750 supervisor was booted from a non-console disk, it came up with cache turned off (VMB was turning it off). The supervisor now turns the cache on when it is booted or started from 10000.

3. If you turned memory management on (SET MM ON), a RUN or START command occasionally would fail with an "Interrupt stack not valid" halt code (04). This would have occurred most on the slower VAXes (11/730). This has been fixed.

1.4 Known Bugs And Deficiencies

1. When running the supervisor in the on-line mode (under VMS), the supervisor's default load device/directory is set to the first equivalence value returned for the SYS$SYSROOT logical name, plus the string [SYSMAINT]. Normally, this will equate to the system disk plus [SYS0.SYSMAINT], e.g. DRA0:[SYS0.SYSMAINT]. If you have arranged diagnostics in a search list structure, you can SET LOAD to a logical name which is equivalent to the desired search list. For example,

```
SET LOAD SYS$MAINTENANCE:
```

RELEASE NOTES FOR
VAX-11 DIAGNOSTIC SUPERVISOR
VERSION 8.1
Mar. 31, 1985

I ANNOUNCING A NEW SUPERVISOR, EDSAA, TO SUPPORT THE VAX-8600!

1.1 New Features Include:

o Dual SBI system, SBIA0 and SBIA1, that must be attached to the hub, which is an ABUS, for the 8600. MBA, UBA and CI adapters are then attached to either SBIA0(SI0), or SBIA1(SI1).

For example, ATTACH SBIA HUB SI0
ATTACH SBIA HUB SI1

Then any adapter is attached to either SI0 or SI1.

With a dual SBI configuration on the 8600, it is possible to have a maximum of 8 Unibus's, 4 on each SBI. To accomodate this situation, changes were made to the DW780 Ptable macro. The number of units was changed to accept 8 maximum. Since 3 bits are needed to specify attaching of DW0-DW7, and the DW780 macro only stores the lower two bits of _DRIVE into the _DVA field, the Unibus address space translates as follows: (using a CSR of 760000)

Unibus 0 and 4 = 2013E000

Unibus 1 and 5 = 2017E000

Unibus 2 and 6 = 201BE000

Unibus 3 and 7 = 201FE000

The recommended way of attaching 8 DW780'S:

for SBIA 0, DW0, DW1, DW2, or DW3,

for SBIA 1, DW4, DW5, DW6, or DW7.

WARNING: DW0 and DW4 should not be attached to the same SBIA since they translate to the same Unibus address space. Likewise for DW1 and 5, DW2 and 6, and DW3 and 7.

o Support for the Environmental Monitoring Module, EMM, is included in this supervisor. If any alerts are received from the EMM module from a power supply, temperature sensor, or air blower, the VDS will report a message on the console and

then resume operation.

- This supervisor can be booted and controlled from a remote terminal. To make a remote connection, the terminal control switch of the CPU must be set to REMOTE, and a modem must be connected to the rear async-panel port. Then the user can dial-up the cpu and remote connection will occur. The supervisor can be booted from the remote terminal by the usual commands. If the supervisor has already been booted from the CTY, make the remote connection, type "^P" from the remote terminal, then "CONT".

  Note that terminal input from local or remote consoles will be echoed on both! Thus, if you are using the remote terminal, you can send messages to a user at the local terminal, and vice versa, by prefixing the message with a "!", which indicates a comment line to the supervisor's command parser.

  Also note that command input from both console terminals is not separated by the diagnostic supervisor, so if both users type a command at the same time, the diagnostic supervisor will see a garbled command and report that an illegal command was typed.

1.2 New Features

1. Several new p-tables have been added. They are: DHU11, DHV11, DR11C, DX20, TU70, and TU72.

2. The number of terminals that can be attached has been increased from 8 to 255 to better support LAT configurations.

1.3 Bug Fixes

1. The /NOALLOCATE switch has been fixed to modify the complete list of devices specified, not just the first device in the list.

2. Previously, when SET P was entered, the supervisor would assume that this was short for SET PROMPT. This is an ambiguity however, since there is also a SET PAGE command. Now, more than just the leading P must be entered to make the command unique.

RELEASE NOTES FOR VAX-11 DIAGNOSTIC SUPERVISOR VERSION 8.2 June 24, 1985

1 NEW FEATURES

1. The number of UNA11 units that can be attached has been increased from 1 to 8.

2 BUG FIXES

1. When booting from a disk connected to an HSC50 which is connected to a CI780 or CI750, the ptable for the CI750/CI780 would sometimes contain the incorrect values for BR and slot number. This has been fixed.

2. When booting from a CI750 disk, the CI750 ptable (PAa0) device name may have been incorrect. This has been fixed.

3 KNOWN BUGS

1. None.

RELEASE NOTES FOR
VAX-11 DIAGNOSTIC SUPERVISOR
VERSION 8.3
September 23, 1985

1. NEW FEATURES:

1. /BASE and /NOBASE Qualifiers:

The /NOBASE qualifier allows zero to be used in the address calculation for the given command, instead of the default base address.

The /BASE:temp_base allows a temporary base address to be used in the address calculation for the given command, instead of the default base address.

These new qualifiers affect the commands which use the base address set by the SET BASE command: DEPOSIT, EXAMINE, SET BREAKPOINT, and CLEAR BREAKPOINT.(q(_.PARAGRAPH On SET, and CLEAR BREAKPOINT, the /NOBASE qualifier can be abbreviated to /N. For EXAMINE and DEPOSIT, /NOBASE can be abbreviated to /NO, thus keeping /N as the abbreviation for /NEXT:n.

On SET, and CLEAR BREAKPOINT, the /BASE:temp_base qualifier can be abbreviated to /B. For EXAMINE and DEPOSIT, /BASE:temp_base can be abbreviated to /BA:temp_base, thus keeping /B as the abbreviation for /BYTE.

These qualifiers may be placed anywhere on the command line after the command name.

EXAMPLE:

```
SET BASE 100                        ! Sets Default Base.
DEPOSIT /BASE:200 44 555            ! Address is 244.
EXAMINE /NOBASE 244                 ! Address is 244.
   00000244:     555
```

2. New Ptables:

New Ptables have been added for: LN03, LA210, VT61, VT71, VT131, and VT132.

2. Bug Fixes:

1. Console Boot Driver HALT:

If an attempt was made to load a file from the console device when mapping is enabled, the VDS would halt in the console boot driver in the routine DO_MAPPING where physical to virtual mapping would occur, but is not

implemented yet. This problem has been corrected.

2. Online as Subprocess Hang:

   A bug was fixed that was causing the Diagnostic Supervisor to hang when run on-line as a sub-process, communicating via a mailbox. Additionally, the SET WIDTH command will return an error message when run with a mailbox as output.

3. HSC Failover:

   VMB uses bits <15:08> and <07:00> to test for failover to an "alternate" HSC. Diagboot and the Diag Super expect the low byte [<7:0>] to be the "first try" HSC, but VMB uses the second byte [<15:08>] as the "first try" HSC, if the second byte is NON ZERO. If there is a non-zero value in the second byte in R2, the Diag Super will not load, run or get directories in Sysmaint.

   The problem has been resolved by having VDS use the method that VMB uses, as described above.

3. Known Bugs:

   1. NONE.

RELEASE NOTES FOR VAX-11 DIAGNOSTIC SUPERVISOR VERSION 9.0 Dec. 23, 1985

1. Announcing a new supervisor, EBSAA, to support the VAX-8200!

This version, 9.0, contains the 8200 supervisor. Support includes:

o A new processor (device type KA820) which contains 4 SLU's (Serial Line Units), a new backplane interconnect called the VAXBI, and a UNIBUS adapter (device type DWBUA) and a BI to SDI adapter (device type KDB50). The KDB50 is used to interface to RA60, RA80, RA81, and RA82 type disks. Since the VAXBI is known as the HUB, these adapters are attached as follows:

```
DS>
DS> ATTACH KA820 HUB KA0   ! cpu
K-bytes of Main Memory? 1024
BI Node Number (HEX)? B
DS>
DS> ATTACH SLU KA0 TCA0
Serial Line Externally Wrapped? Yes
Baud Rate? 9600
DS>
DS> ATTACH DWBUA HUB DW0   ! UNIBUS adapter
BI Node Number (HEX)? 2
B? 4
DS>
DS> ATTACH KDB50 HUB DUA   ! KDB50 adapter
BI Node Number (HEX)? 7
B? 5
```

o Customer Runnable Diagnostics are not supported on the 8200. The console boot command: T/M, which would ordinarily start CRD in Menu mode, boots the Vax Diagnostic Supervisor.

o The $DS_CHANNEL service has been enhanced to support BI adapters.

- The INITA function supports the BUA and the KDB50. It also accepts as an optional argument, time, which is the number of ten-milliseconds to wait for the BI node self-test to complete. If the time argument is not specified, a default of 100 milliseconds is used for the BUA, and 10 seconds for the KDB50.

- There are two new functions, SELF_TEST and STOP, which are used only for BI adapters. SELF_TEST will initiate the self-test for any BI adapter. This function also accepts the time argument (default is 10 seconds).

The STOP function stops a BI adapter from issuing any more BI transactions.

- The STATUS and ENINT functions accept a new argument (bistsadr) which specifies the address of a quadword which returns the BIIC CSR and the BIIC BER.

- The MACRO-32 format is now:

  $DS_CHANNEL_x, unit, func, [vecadr], [stsadr], [time], [bistsadr]

- The BLISS-32 format is:

```
$DS_CHANNEL (UNIT=unit, FUNC=func, [VECADR=vecadr], [STSADR=stsadr],
                [TIME=time], [BISTSADR=bistsadr]);
```

- Two new return codes have been defined: DS$_BIIC indicates that the BIIC self-test has failed, and DS$_NODE indicates that the BI node self-test failed.

- In addition to the following fields in status-1,

```
CHS$V_SYSERR
CHS$V_CHNERR
CHS$V_DEVERR
CHS$V_PGMERR
CHS$V_DEVBUS
CHS$V_PGMHDE
CHS$V_BUSPDN
CHS$V_BUSNXM,
```

  the following new bits have been defined:

  CHS$V_UIE - Bit 28 - UNIBUS Interlock Error; set if a DATO(B) does not follow a DATIP transaction on the UNIBUS.

  CHS$V_BADBDP - Bit 29 - Bad Buffered Data Path; set if data path 6 or 7 is selected.

  CHS$V_BADPAR - Bit 30 - Set if RAM parity error occurred.

- The bistsadr argument points to a quadword which contains 2 longwords. The first is the BIIC Control and Status Register. The second is the BIIC Bus Error Register. Bit definitions are defined by the $BIICDEF macro. Bit definitions are as follows:

  BIIC CSR: BIIC Control and Status Register

  BIIC$V_NODE_ID,BIIC$S_NODE_ID - Bits 0-3 - Node ID
  BIIC$V_ARBCNTL,BIIC$S_ARBCNTL - Bits 4-5 - Arbitration Mode
  BIIC$V_SEIE,BIIC$M_SEIE - Bit 6 - Soft Error Interrupt Enable
  BIIC$V_HEIE,BIIC$M_HEIE - Bit 7 - Hard Error Interrupt Enable
  BIIC$V_UWP,BIIC$M_UWP - Bit 8 - Unlock Write Pending

```
BIIC$V_SST,BIIC$M_SST - Bit 10 - Start Self_Test
BIIC$V_STS,BIIC$M_STS - Bit 11 - Self-Test Status
BIIC$V_BROKE,BIIC$M_BROKE - Bit 12 - Broke
BIIC$V_INIT,BIIC$M_INIT - Bit 13 - Init
BIIC$V_SES,BIIC$M_SES - Bit 14 - Soft Error Summary
BIIC$V_HES,BIIC$M_HES - Bit 15 - Hard Error Summary
BIIC$V_BIICTYPE,BIIC$S_BIICTYPE - Bits 16-23 - BIIC Interface
                                              Type
BIIC$V_BIICREVN,BIIC$S_BIICREVN - Bits 24-31 - BIIC Interface
                                              Revision

BIIC BER:  BIIC Bus Error Register

BIIC$V_NPE,BIIC$M_NPE - Bit 0 - Null Bus Parity Error
BIIC$V_CRD,BIIC$M_CRD - Bit 1 - Corrected Read Data
BIIC$V_IPE,BIIC$M_IPE - Bit 2 - ID Parity Error
BIIC$V_UPEN,BIIC$M_UPEN - Bit 3 - User Parity Enable
BIIC$V_ICE,BIIC$M_ICE - Bit 16 - Illegal Confirmation Error
BIIC$V_NEX,BIIC$M_NEX - Bit 17 - Non-Existent Address
BIIC$V_BTO,BIIC$M_BTO - Bit 18 - Bus Timeout
BIIC$V_STO,BIIC$M_STO - Bit 19 - Stall Timeout
BIIC$V_RTO,BIIC$M_RTO - Bit 20 - Retry Timeout
BIIC$V_RDS,BIIC$M_RDS - Bit 21 - Read Data Substitute
BIIC$V_SPE,BIIC$M_SPE - Bit 22 - Slave Parity Error
BIIC$V_CPE,BIIC$M_CPE - Bit 23 - Command Parity Error
BIIC$V_IVE,BIIC$M_IVE - Bit 24 - IDENT Vector Error
BIIC$V_TDF,BIIC$M_TDF - Bit 25 - Transmitter During Fault
BIIC$V_ISE,BIIC$M_ISE - Bit 26 - Interlock Sequence Error
BIIC$V_MPE,BIIC$M_MPE - Bit 27 - Master Parity Error
BIIC$V_CTE,BIIC$M_CTE - Bit 28 - Control Transmit Error
BIIC$V_MTCE,BIIC$M_MTCE - Bit 29 - Master Loopback Error
BIIC$V_NMR,BIIC$M_NMR - Bit 30 - NOACK to multi-responder
                                 command Received
```

- The message which is printed when an unexpected interrupt occurs from a BI adapter (SCB vectors 100 - 1FC) has been changed to include the BI node number, and the contents of that node's Bus Error Register with a bit-to-text translation.

- When a machine check stack frame is printed, if the BI ERROR bit (4) in the machine check typecode longword is set, the cpu's Bus Error Register is also included.

- The duration of the boot process may vary because it runs self-test on all adapters on the system except the cpu and memory.

2. Vax Diagnostic Supervisor Support for the 8650.

EDSAA has been updated to include support for the 8650. The 8650 represents a 44% speed improvement over the 8600, plus larger 32 M memory boards.

3. Vax Diagnostic Supervisor Support under ULTRIX.

   o Standalone ULTRIX is fully supported in all Supervisors linked now. Any disk for which VDS supports the ODS file structure is automatically supported for ULTRIX. Operation is the same except for the following changes made for the DIRECTORY, LOAD, SET LOAD and RUN commands. ALL VDS COMMAND MAY BE UPPER OR LOWER CASE LETTERS.

   o Legal filename for VDS ULTRIX directories and files can include the symbols A-z, 0-9,. . and * or % for wildcard matching.

   o BOOTING VDS SYSTEMS:

     Booting is the same as now except that your default directory will be ddan:(0,p)field unless the directory value is found in the RPB$T_FILE file of the RPB in which case that will be used. The exception to this is the 11/750 system. The command 'B/60000010' is used instead of 'B/10' in order to set the partition to '6'.

     For the 11750 you use "B/60000010" and that boots the device selected by the switch on the front panel. For the 8200 you use "B/R5:60000010". The boot cmd files for the 11/730 has a "D RB 60000010" command in it which does a deposit to R11 to boot VDS. The 11/780/785 boot cmd files have a "D R11 60000010" command in them to boot VDS under ULTRIX.

   o SET LOAD:

     To run from an ULTRIX disk you did not boot from you will have to issue a SET LOAD command of the form ddan:(0,p)directory. The parentheses and enclosed information are required if you are currently running from an ODS disk. The '0' is a ULTRIX unit number which is not currently implemented and therefore set to 0. The p is a partition number and is generally set to 6 for partition 'G'. The 'directory' value is generally set to 'field' for diagnostics but can be any values (for examples, usr, WORD, field/user/source). The '/' is a delimiter and is use to separate directory names. If you are currently in ULTRIX mode, you can return to the VMS compatible mode by giving a SET LOAD with ddan:[name] where the brackets and directory are required to change over. Once in ULTRIX mode any of the following are valid:

     SET LOAD ddan:(0,p)field/user
     SET LOAD (0,p)field/user

SET LOAD field/user

If a device or '(0,p)' is not specified they are not changed.

o DIRECTORY:

The directory command has several items to note. Assume you have the files evdba.exe and evkab.hlp in the directory DMA0:(0,6)field If you enter DIRECTORY you will get:

evkab.exe evkab.hlp

total of 2 files.

As output. If you do a SET LOAD to field/evkab.exe and then enter the DIRECTORY command you will get

evkab.exe

total of 1 files.

The system will automatically check if the last link given is a valid directory and if not will back up to the previous link and assume you are looking for one particular file which it finds. This is what you would also get if your directory was 'field' and you entered any of the following:

DIRECTORY evkab.exe
DIRECTORY field/evkab.exe
DIRECTORY (0,6)field/evkab.exe
DIRECTORY DMA0:(0,6)field/evkab.exe

Wildcard are support as for ODS disks, but you should be aware that NO DEFAULTS ARE ASSUMED. An ULTRIX file spec does not have the required format of a VMS type file. You will have to enter the name and extension with either actual or wildcard values. The wildcard name may be any combination of upper or lower case letters. The results from a DIRECTORY command will yield all matching files without regards to upper or lower case letters.

o LOAD or RUN:

These commands work similar as before. If you specify a directory link with the file name, you must give the entire string of links. For example if your file eckam.exe is in DMA0:(0,6)field/usr/word directory, and you have done a SET LOAD to this, the command LOAD word/eckam.exe will not work. Any of the following commands will work.

LOAD eckam.exe

```
LOAD field/usr/word/eckam.exe
LOAD (0,6)field/usr/word/eckam.exe
LOAD DMA0:(0,6)field/usr/word/eckam.exe
```

The same format is valid for RUN also.

o RMS protocols:

ULTRIX files do not have a structure like VMS files. However support has been added to make all the old commands be compatible. Sequential and Random (by RFA) access is supported.

1. $OPEN

   If you do an $OPEN on a file with the last 4 characters of its $FAB DNM set to .dir (letters any case) the file you get will be the directory the file is in unless it is a directory is which case you will get it.

2. $READ

   This will read in the file to the location you specified. You will have to do any necessary file structure interpretation.

3. $GET

   If the opened file has the last 4 characters of its $FAB DNM set to .hlp or to the length of the line. If the opened file has the last 4 characters of its $FAB DNM set to .dir (letters any case) this will yield a 'record' of the form:

   If anything else is specified for DNM you will get 512 bytes or remaining bytes in the files and you interpret the structure.

This information is subject to change for compatibility with the online support and updates to ULTRIX. Welcome to the world of ULTRIX.

4. A new supervisor service, $DS_PRINTREV has been added.

   The Print Revision Level service may be used in diagnostic programs that test devices for which a hardware, firmware, and/or patch revision level is accessible to the program. Such programs may want to indicate whether the device's revision levels are compatible with the revision levels expected by the program.

   This service will:

   - Compare actual and expected device revision levels specified by the diagnostic program
   - Display a message indicating the device's revision level (hardware firmware, or patch), and also indicating whether the revision levels being compared are hardware levels, firmware levels, or patch levels. A module number may be printed, and hardware revision numbers may be converted to a letter code.
   - Cause the hardware revision level, firmware revision level and/or patch level to be included in all error messages (generated via $DS_ERRxxxx macros) that are subsequently displayed for the unit in question.

   If the device being tested has a software-readable hardware, firmware, or patch level, the $DS_PRINTREV service should be called for each selected device. This call(s) should be made in the "pass 0" section of the initialization code.

   If the device has all three (hardware, firmware, and patch) revision types, then the service should be called three times for each selected device; once to report the hardware revision, once for the firmware revision, and once for the patch level. For each logical unit, $DS_PRINTREV can be called four times for each type of revision level. For example, it would be desirable to call $DS_PRINTREV twice for hardware revision levels if a logical unit was a 2-board device, and each board had an associated hardware revision level.

   When called, the service will (at the programmer's option) immediately display a message indicating the actual revision level and/or messages indicating whether the actual revision level matches the revision level expected by the diagnostic program. One of the following messages may be printed. (DEVNAME will be replaced by the generic name of the unit in question.)

```
Hardware revision level of DEVNAME (T1002):    ******
Hardware revision level of DEVNAME (T1002) is less than that expected by
diagnostic program.
        Hardware revision level:               ******
        Revision level expected by program:    ******

Hardware revision level of DEVNAME (T1002) is equal to that expected by
diagnostic program.
        Hardware revision level:               ******
        Revision level expected by program:    ******

Hardware revision level of DEVNAME (T1002) is greater than that expected by
diagnostic program.
        Hardware revision level:               ******
        Revision level expected by program:    ******
If firmware or patch levels are being reported, the word
"hardware" in the messages will be replaced with the word
"firmware" or "patch".

If the modulenum argument has been passed, the module number
will be printed for the hardware, firmware, and patch
messages associated with that module number. If the number
is not passed, it will not appear in the above messages.

Each time an error service is called ($DS_ERRxxxx) for a unit
for which the $DS_PRINTREV macro has been called, the
hardware revision level, and/or firmware revision level
and/or patch level will be displayed as part of the error
message. The message will be displayed AFTER all of the
error text has been printed. It will be inhibited if the IE1
flag is set. The format of this display will be:
******  program title          program rev. ******
Pass #, test #, subtest #, error #, date
Hard error while testing DEVNAME:  text

        text

Revision level(s) for DEVNAME:
        (T1002): Hardware = X; Firmware = X; Patch = X;
        (T1003): Hardware = Y; Firmware = Y; Patch = Y;

****** End of hard error number # ******

(If any of the levels or the module number are not being
reported, they will not appear in the revision level
message.)

MACRO-32 Format:

        $DS_PRINTREV_x log_unit, actual_rev, expected_rev, rev_type,
                              [printmask], [prlink], [modulenum]
```

BLISS Format:

```
$DS_PRINTREV   (LOG_UNIT=log_unit, ACTUAL_UNIT=actual_rev,
                        EXPECTED_REV=expected_rev, REV_TYPE=rev_type,
                        [PRINTMASK=printmask], [PRLINK=prlink],
                        [MODULENUM=modulenum]);
```

log_unit

Logical unit number of device whose revision level is to be checked.

actual_rev

Longword containing the actual hardware, firmware, or patch revision level for the device whose logical unit number is specified with the "logunit" parameter. See note 4. (The diagnostic program determines this value by accessing the hardware.)

expected_rev

Longword containing the hardware, firmware, or patch revision level which was expected by the diagnostic program. See note 4. (This value is placed in the diagnostic program at compilation time.)

rev_type

Longword mask indicating the type of revision code (hardware, firmware, or patch) being compared. Bit definitions are:

- Bit 0 - PRVV_HWREV,PRVM_HWREV - Set this bit to indicate a hardware revision level.
- Bit 1 - PRVV_FWREV,PRVM_FWREV - Set this bit to indicate a firmware revision level.
- Bit 2 - PRVV_PREV,PRVM_PREV - Set this bit to indicate a patch level.

(Only one bit should be set per service call.)

printmask

Longword mask used to control $DS_PRINTREV functions. Bit definitions are:

- Bit 0 - PRMSK$V_LSS,PRMSK$M_LSS - if set, inhibits message that would normally be displayed if the actual revision is less than expected.

- Bit 1 - PRMSK$V_EQL,PRMSK$M_EQL - if set, inhibits message that would normally be displayed if the actual revision is equal to that expected.

- Bit 2 - PRMSK$V_GTR,PRMSK$M_GTR - if set, inhibits message that would normally be displayed if the actual revision is greater than expected.

- Bit 3 - PRMSK$V_ALWAYS,PRMSK$M_ALWAYS - if set, displays the message which lists only the actual revision level.

- Bit 4 - PRMSK$V_TRANSL,PRMSK$M_TRANSL - if set, will convert a hardware revision number to a letter code which represents the functional revision as defined by DEC STD 012. Setting this bit will not result in conversion for firmware or patch revisions. The conversion pattern is shown in table 1. See note 6.

Table 1: Revision Number to Letter Conversion

Field contents [bits <n:0>]	Functional Rev.
0.....0000	pre-release
0.....0001	A
0.....0010	B
0.....0011	C
.	.
.	.
0....11010	Z
0....11011	AA
0....11100	AB
0....11101	AC
.	.
.	.
0...110100	AZ
0...110101	BA
.	.
.	.
0..1001110	BZ
.	.
.	.
1010111110	ZZ

For example, if only bits 1 and 2 are set then a message will be displayed only if the actual revision is less than that expected by the program.

By default, bits 0, 1, 2, 3, and 4 are clear, in which case no conversion will be performed on revision numbers. In addition, a message will be displayed stating whether the actual revision is greater than, less than, or equal to the revision expected by the program. Inhibiting messages does not affect the inclusion of the hardware, firmware or patch revision levels in error messages generated by $DS_ERRxxxx macros.

prlink

Address of a message routine. This optional routine will have the same format as an error reporting routine used with a $DS_ERRxxxx macro. That is, the routine should be delineated with $DS_BGNMESSAGE and $DS_ENDMESSAGE macros and should use $DS_PRINTB and $DS_PRINTX macros for displaying text.

modulenum

Address of a counted ASCII string which represents the unique module number for a board (e.g. "T1002"). If you supply this argument for a hardware revision, then you must supply the same argument for any firmware or patch revision associated with that module.

Notes:

1. Symbols are defined by the $DS_PRINTREV_DEF macro.

2. This macro should only be used for devices having software-accessible hardware, firmware, or patch revision numbers.

3. Some programmer's may want the text displayed only in certain circumstances. For example, perhaps it is the concensus of a particular program's users that the text only be displayed if the actual revision level is lower than that expected by the diagnostic program. In such a case, the "printmask" parameter may be used to inhibit one or more of the possible warning messages.

4. The format of the revision level is irrelevant, but the values passed via the "actual_rev" and "expected_rev" parameters must be in the same format. The service will perform an unsigned comparison of the two values to determine which message to display. Revision numbers will be displayed as unsigned decimal values unless conversion to a letter code is desired.

5. This macro should be used to determine whether current versions of diagnostics are incompatible with old hardware. Since new diagnostics may only run on hardware above a certain revision level, the diagnostic should only set bits 1 and 2 in printmask. This causes a message to be displayed only if the actual revision level is less than that expected by the program.

6. Normally, the hardware revision level should be converted to the corresponding functional revision letter code by setting bit 4 in printmask.

7. If you do not set bit 2 in printmask, a misleading message may result if the actual hardware, firmware, or patch levels were updated without a corresponding change to the diagnostic's expected revision levels.

5. Additions & Fixes.

1. Support has been added for new devices: RD52, RD53, RA82, and LUA11.

2. Channel service for DSINT was returning SS$_NORMAL when DSINT was documented as returning DS$_NORMAL. This has been corrected.

3. A new control flag, AskPrompt, has been added in order to support the new Automated Test and Verification system, SAVES/AVS. When this flag is set, a special prompt, "ASK>", is appended to the user's prompt which was specified for any of the $DSASKxxxx macros. The flag is clear by default.

6. Known Bugs and Deficiencies:

1. The console command language uses the device names CSA1 and CSA2 for the console floppy drives. The supervisor, however, always refers to drive CSA1 as CSA0. Furthermore, although the supervisor can be booted from either floppy drive, files can only be accessed from CSA1. This will be fixed in a future release.

2. When the supervisor is booted, it attempts to automatically ATTACH all of the devices in the boot path. In order to do this, a certain amount of sizing must be done in order to determine the controller letter and drive number of the device name for the disk which was booted from. If you have more than one UDA50 configured on the system, or a combination of UDA50s and KDB50s, and you boot from a disk other than a disk which is connected to the adapter with the lowest node id, the controller letter portion of the device name will not agree with the controller letter assigned by the autosizer.

3. Ultrix mode problems:

1. Some commands are recognized in upper case only. All commands are recognized in upper case, so this is the temporary work-around.

2. Ultrix differentiates between upper and lower case in file names. The VDS maintains this distinction. Therefore, the case of each letter must be correct in order for the VDS to find the file.

3. The Ultrix file system does not support file version numbers as does VMS. Like-wise, the VDS does not support version numbers when referencing Ultrix file systems. Version numbers are sometimes created by the DECnet-Ultrix dcp command. Any files with version numbers must be renamed. Under Ultrix, this is done with the mv command; specifying the file name in single quotes for it to accept the version number. For example: mv 'ECSAA.EXE;1' ecsaa.exe.

4. All scripts run by the VDS must have their file names in upper case. For example, ATT.COM, not att.com.

5. When specifying a file name to the VDS, the complete file name must be specified. For example, @ATT.COM or RUN evsba.exe.

6. If a non-system disk is being used as the load device, that disk must have file systems on both the a and g partitions, with the files wanted in the g partition's file system. No links have to exist between these file systems, however. A file system is created with the Ultrix newfs command. Care must be used, as this command is similar to the VMS INITIALIZE command and will destroy data on the disk.

7. The VDS INITPCS command does not work.

8. When specifying command modifiers, they must be placed on the command verb and not on the file name. For example, use RUN/TEST:3:4 evkab.exe, not RUN evkab.exe/TEST:3:4. The / used to indicate a command modifier to the VDS is also used in Ultrix as part of a file specification.

RELEASE NOTES FOR VAX-11 DIAGNOSTIC SUPERVISOR VERSION 9.1 Jan 20,1986

1. Announcing a new supervisor, EZSAA, to support the VAX-8800!

This version, 9.1, contains the 8800 supervisor

o NAUTILUS I/O consists of the new corporate interconnects: BI,NI,SI,CI and will have 4 I/O channels.

The NAUTILUS NMI-BI (NBI) adapter interfaces the NAUTILUS Memory Interconnect (NMI) bus to two backplane Interconnect (BI)busses.

The NBI is partitioned into three main sections,the NMI port,NBI transaction buffer and two BI users ports,the first two sections are contained on an extended hex module mounted in the cpu backplane (NBIA). Each BI user port is contained on a BI Eurocard (NBIB) located in the BI backplane.

Any NAUTILUS will have a maximum of 2 NBIA's,permitting a maximum of 4 seperate BI channels.

EZSAA has also support for the following adapters:

- BUA, a unibus adapter,device type DWBUA
- BLA, BI to LESI adapter,device type DWBLA. This adapter is primarily intended for TAPE interface on NAUTILUS systems.
- BCI, CI to BI computer interconnect,device type CIBCI.
- BDA, BI to SDI adapter,device type KDB50 The BDA is the primary disk controller for NAUTILUS and will provide the pathway to SI based disks only.

The NMI is known as the HUB,these adapters are attached as follows:

```
DS>
DS> ATTACH KA880 HUB KA0            ! cpu
PRIMARY ? YES
DS>
DS> ATTACH NBIA HUB NBIA0           ! NBI adapter
LOGICAL ADAPTER # 0
DS>
DS> ATTACH NBIB NBIA0 NBIB0         ! NBI adapter
BI # ? 0
```

```
BI Node Number (HEX) ? 2
DS>
DS> ATTACH NBIB NBIA0 NBIB1          ! NBI adapter
BI # ? 1
BI Node Number (HEX) ? 3
DS>
DS>
DS> ATTACH NBIA HUB NBIA1            ! NBI adapter
LOGICAL ADAPTER # 1
DS>
DS> ATTACH NBIB NBIA1 NBIB2          ! NBI adapter
BI # ? 0
BI Node Number (HEX) ? 0
DS>
DS> ATTACH NBIB NBIA1 NBIB3          ! NBI adapter
BI # ? 1
BI Node Number (HEX) ? 1
DS>
DS>
DS> ATTACH DWBUA NBIB0 DW0           ! BUA adapter
BI Node Number (HEX) ? 5
BR ? 4
DS>
DS> ATTACH DWBLA NBIB0 BLA0          ! BLA adapter
BI Node Number (HEX) ? 6
DS>
DS> ATTACH CIBCI NBIB0 PAA0          ! BCI adapter
BI Node Number (HEX) ? 7
BR ? 5
CI Node ? 2
DS>
DS> ATTACH KDB50 NBIB0 DUA ! BDA adapter
BI Node Numbe (HEX) 8
BR ? 6
DS>
```

The LOGICAL ADAPTER #,BI # and the BI Node Number are not arbitrary values, but are based upon the NAUTILUS system I/O configuration, these values are used by the supervisor to construct the device address for each NBIA and BI node that is attached and therefore must be known at attach time.

However,the adapter's drive numbers don't require that restriction,but, because of Vax Diagnostic Supervisor convention,it is advisable that these numbers are assigned in a sequential order.

o Prior to the loading of diagnostics,a console ASSIGN command must be issued ,this will associate the logical name CSA1 with the winchester RD disk. This ASSIGN command can be done prior to the booting of the supervisor or as described below if the supervisor has already been booted.

```
DS> ^p                      ; back to console mode
>>> halt                    ; halt the processor
>>> assign csa1 dw1:        ; do the assign command
>>> continue                ; back to supervisor control
DS> load EVXXX              ; proceed to load diagnostic
```

o Customer Runnable Diagnostics are not supported on the 8800.

o The $DS_CHANNEL service has been enhanced to support BI adapters.

- The INITA function supports the BUA and the KDB50. It also accepts as an optional argument, time, which is the number of ten-milliseconds to wait for the BI node self-test to complete. If the time argument is not specified, a default of 320 milliseconds is used for the BUA, and 10 seconds for the KDB50.

- There are two new functions, SELF_TEST and STOP, which are used only for BI adapters. SELF_TEST will initiate the self-test for any BI adapter. This function also accepts the time argument (default is 10 seconds).

  The STOP function stops a BI adapter from issuing any more BI transactions.

- The STATUS and ENINT functions accept a new argument (bistsadr) which specifies the address of a quadword which returns the BIIC CSR and the BIIC BER.

- The MACRO-32 format is now:

  ```
  $DS_CHANNEL_x, unit, func, [vecadr], [stsadr], [time],
                 [bistsadr]
  ```

- The BLISS-32 format is:

  ```
  $DS_CHANNEL (UNIT=unit, FUNC=func, [VECADR=vecadr], [STSADR=
               stsadr], [TIME=time], [BISTSADR=bistsadr]);
  ```

- Two new return codes have been defined: DS$_BIIC indicates that the BIIC self-test has failed, and DS$_NODE indicates that the BI node self-test failed.

- In addition to the following fields in status-1,

  ```
  CHS$V_SYSERR
  CHS$V_CHNERR
  CHS$V_DEVERR
  CHS$V_PGMERR
  CHS$V_DEVBUS
  CHS$V_PGMHDE
  CHS$V_BUSPDN
  ```

CHS$V_BUSNXM,

the following new bits have been defined:

CHS$V_UIE - Bit 28 - UNIBUS Interlock Error; set if a DATO(B) does not follow a DATIP transaction on the UNIBUS.

CHS$V_BADBDP - Bit 29 - Bad Buffered Data Path; set if data path 6 or 7 is selected.

CHS$V_BADPAR - Bit 30 - Set if RAM parity error occurred.

- The bistsadr argument points to a quadword which contains 2 longwords. The first is the BIIC Control and Status Register. The second is the BIIC Bus Error Register. Bit definitions are defined by the $BIICDEF macro. Bit definitions are as follows:

BIIC CSR: BIIC Control and Status Register

BIIC$V_NODE_ID,BIIC$S_NODE_ID - Bits 0-3 - Node ID
BIIC$V_ARBCNTL,BIIC$S_ARBCNTL - Bits 4-5 - Arbitration Mode
BIIC$V_SEIE,BIIC$M_SEIE - Bit 6 - Soft Error Interrupt Enable
BIIC$V_HEIE,BIIC$M_HEIE - Bit 7 - Hard Error Interrupt Enable
BIIC$V_UWP,BIIC$M_UWP - Bit 8 - Unlock Write Pending
BIIC$V_SST,BIIC$M_SST - Bit 10 - Start Self Test
BIIC$V_STS,BIIC$M_STS - Bit 11 - Self-Test Status
BIIC$V_BROKE,BIIC$M_BROKE - Bit 12 - Broke
BIIC$V_INIT,BIIC$M_INIT - Bit 13 - Init
BIIC$V_SES,BIIC$M_SES - Bit 14 - Soft Error Summary
BIIC$V_HES,BIIC$M_HES - Bit 15 - Hard Error Summary
BIIC$V_BIICTYPE,BIIC$S_BIICTYPE - Bits 16-23 - BIIC Interface Type
BIIC$V_BIICREVN,BIIC$S_BIICREVN - Bits 24-31 - BIIC Interface Revision

BIIC BER: BIIC Bus Error Register

BIIC$V_NPE,BIIC$M_NPE - Bit 0 - Null Bus Parity Error
BIIC$V_CRD,BIIC$M_CRD - Bit 1 - Corrected Read Data
BIIC$V_IPE,BIIC$M_IPE - Bit 2 - ID Parity Error
BIIC$V_UPEN,BIIC$M_UPEN - Bit 3 - User Parity Enable
BIIC$V_ICE,BIIC$M_ICE - Bit 16 - Illegal Confirmation Error
BIIC$V_NEX,BIIC$M_NEX - Bit 17 - Non-Existent Address
BIIC$V_BTO,BIIC$M_BTO - Bit 18 - Bus Timeout
BIIC$V_STO,BIIC$M_STO - Bit 19 - Stall Timeout
BIIC$V_RTO,BIIC$M_RTO - Bit 20 - Retry Timeout
BIIC$V_RDS,BIIC$M_RDS - Bit 21 - Read Data Substitute

```
BIIC$V_SPE,BIIC$M_SPE - Bit 22 - Slave Parity Error
BIIC$V_CPE,BIIC$M_CPE - Bit 23 - Command Parity Error
BIIC$V_IVE,BIIC$M_IVE - Bit 24 - IDENT Vector Error
BIIC$V_TDF,BIIC$M_TDF - Bit 25 - Transmitter During Fault
BIIC$V_ISE,BIIC$M_ISE - Bit 26 - Interlock Sequence Error
BIIC$V_MPE,BIIC$M_MPE - Bit 27 - Master Parity Error
BIIC$V_CTE,BIIC$M_CTE - Bit 28 - Control Transmit Error
BIIC$V_MTCE,BIIC$M_MTCE - Bit 29 - Master Loopback Error
BIIC$V_NMR,BIIC$M_NMR - Bit 30 - NOACK to multi-responder
                                 command Received
```

2. A new supervisor service, $DS_PRINTREV has been added.

   The Print Revision Level service may be used in diagnostic programs that test devices for which a hardware, firmware, and/or patch revision level is accessible to the program. Such programs may want to indicate whether the device's revision levels are compatible with the revision levels expected by the program.

   This service will:

   - Compare actual and expected device revision levels specified by the diagnostic program
   - Display a message indicating the device's revision level (hardware firmware, or patch), and also indicating whether the revision levels being compared are hardware levels, firmware levels, or patch levels. A module number may be printed, and hardware revision numbers may be converted to a letter code.
   - Cause the hardware revision level, firmware revision level and/or patch level to be included in all error messages (generated via $DS_ERRxxxx macros) that are subsequently displayed for the unit in question.

   If the device being tested has a software-readable hardware, firmware, or patch level, the $DS_PRINTREV service should be called for each selected device. This call(s) should be made in the "pass 0" section of the initialization code.

   If the device has all three (hardware, firmware, and patch) revision types, then the service should be called three times for each selected device; once to report the hardware revision, once for the firmware revision, and once for the patch level. For each logical unit, $DS_PRINTREV can be called four times for each type of revision level. For example, it would be desirable to call $DS_PRINTREV twice for hardware revision levels if a logical unit was a 2-board device, and each board had an associated hardware revision level.

When called, the service will (at the programmer's option) immediately display a message indicating the actual revision level and/or messages indicating whether the actual revision level matches the revision level expected by the diagnostic program. One of the following messages may be printed. (DEVNAME will be replaced by the generic name of the unit in question.)

```
Hardware revision level of DEVNAME (T1002):    ******
Hardware revision level of DEVNAME (T1002) is less than that expected
by diagnostic program.
        Hardware revision level:                ******
        Revision level expected by program:     ******

Hardware revision level of DEVNAME (T1002) is equal to that expected
by diagnostic program.
        Hardware revision level:                ******
        Revision level expected by program:     ******

Hardware revision level of DEVNAME (T1002) is greater than that
expected by diagnostic program.
        Hardware revision level:                ******
        Revision level expected by program:     ******
```

If firmware or patch levels are being reported, the word "hardware" in the messages will be replaced with the word "firmware" or "patch".

If the modulenum argument has been passed, the module number will be printed for the hardware, firmware, and patch messages associated with that module number. If the number is not passed, it will not appear in the above messages.

Each time an error service is called ($DS_ERRxxxx) for a unit for which the $DS_PRINTREV macro has been called, the hardware revision level, and/or firmware revision level and/or patch level will be displayed as part of the error message. The message will be displayed AFTER all of the error text has been printed. It will be inhibited if the IEI flag is set. The format of this display will be:

```
******  program title          program rev. ******
Pass #, test #, subtest #, error #, date
Hard error while testing DEVNAME:  text

        text

Revision level(s) for DEVNAME:
        (T1002): Hardware = X; Firmware = X; Patch = X;
        (T1003): Hardware = Y; Firmware = Y; Patch = Y;

****** End of hard error number # ******
```

(If any of the levels or the module number are not being reported, they will not appear in the revision level message.)

MACRO-32 Format:

```
$DS_PRINTREV_x log_unit, actual_rev, expected_rev, rev_type,
                        [printmask], [prlink], [modulenum]
```

BLISS Format:

```
$DS_PRINTREV   (LOG_UNIT=log_unit, ACTUAL_UNIT=actual_rev,
                        EXPECTED_REV=expected_rev, REV_TYPE=rev_type,
                        [PRINTMASK=printmask], [PRLINK=prlink],
                        [MODULENUM=modulenum]);
```

log_unit

Logical unit number of device whose revision level is to be checked.

actual_rev

Longword containing the actual hardware, firmware, or patch revision level for the device whose logical unit number is specified with the "logunit" parameter. See note 4. (The diagnostic program determines this value by accessing the hardware.)

expected_rev

Longword containing the hardware, firmware, or patch revision level which was expected by the diagnostic program. See note 4. (This value is placed in the diagnostic program at compilation time.)

rev_type

Longword mask indicating the type of revision code (hardware, firmware, or patch) being compared. Bit definitions are:

- Bit 0 - PRVV_HWREV,PRVM_HWREV - Set this bit to indicate a hardware revision level.
- Bit 1 - PRVV_FWREV,PRVM_FWREV - Set this bit to indicate a firmware revision level.
- Bit 2 - PRVV_PREV,PRVM_PREV - Set this bit to indicate a patch level.

(Only one bit should be set per service call.)

printmask

Longword mask used to control $DS_PRINTREV functions. Bit definitions are:

- Bit 0 - PRMSK$V_LSS,PRMSK$M_LSS - if set, inhibits message that would normally be displayed if the actual revision is less than expected.
- Bit 1 - PRMSK$V_EQL,PRMSK$M_EQL - if set, inhibits message that would normally be displayed if the actual revision is equal to that expected.
- Bit 2 - PRMSK$V_GTR,PRMSK$M_GTR - if set, inhibits message that would normally be displayed if the actual revision is greater than expected.
- Bit 3 - PRMSK$V_ALWAYS,PRMSK$M_ALWAYS - if set, displays the message which lists only the actual revision level.
- Bit 4 - PRMSK$V_TRANSL,PRMSK$M_TRANSL - if set, will convert a hardware revision number to a letter code which represents the functional revision as defined by DEC STD 012. Setting this bit will not result in conversion for firmware or patch revisions. The conversion pattern is shown in table 1. See note 6.

Table 1: Revision Number to Letter Conversion

Field contents [bits <n:0>]	Functional Rev.
0.....0000	pre-release
0.....0001	A
0.....0010	B
0.....0011	C
.	.
.	.
0....11010	Z
0....11011	AA
0....11100	AB
0....11101	AC
.	.
.	.
0...110100	AZ
0...110101	BA
.	.
.	.
0..1001110	BZ
.	.
.	.
1010111110	ZZ

For example, if only bits 1 and 2 are set then a message will be displayed only if the actual revision is less than that expected by the program.

By default, bits 0, 1, 2, 3, and 4 are clear, in which case no conversion will be performed on revision numbers. In addition, a message will be displayed stating whether the actual revision is greater than, less than, or equal to the revision expected by the program. Inhibiting messages does not affect the inclusion of the hardware, firmware or patch revision levels in error messages generated by $DS_ERRxxxx macros.

prlink

Address of a message routine. This optional routine will have the same format as an error reporting routine used with a $DS_ERRxxxx macro. That is, the routine should be delineated with $DS_BGNMESSAGE and $DS_ENDMESSAGE macros and should use $DS_PRINTB and $DS_PRINTX macros for displaying text.

modulenum

Address of a counted ASCII string which represents the unique module number for a board (e.g. "T1002"). If you supply this argument for a hardware revision, then you must supply the same argument for any firmware or patch revision associated with that module.

Notes:

1. Symbols are defined by the $DS_PRINTREV_DEF macro.

2. This macro should only be used for devices having software-accessible hardware, firmware, or patch revision numbers.

3. Some programmer's may want the text displayed only in certain circumstances. For example, perhaps it is the concensus of a particular program's users that the text only be displayed if the actual revision level is lower than that expected by the diagnostic program. In such a case, the "printmask" parameter may be used to inhibit one or more of the possible warning messages.

4. The format of the revision level is irrelevant, but the values passed via the "actual_rev" and "expected_rev" parameters must be in the same format. The service will perform an unsigned comparison of the two values to determine which message to display. Revision numbers will be displayed as unsigned decimal values unless conversion to a letter code is desired.

5. This macro should be used to determine whether current versions of diagnostics are incompatible with old hardware. Since new diagnostics may only run on hardware above a certain revision level, the diagnostic should only set bits 1 and 2 in printmask. This causes a message to be displayed only if the actual revision level is less than that expected by the program.

6. Normally, the hardware revision level should be converted to the corresponding functional revision letter code by setting bit 4 in printmask.

7. If you do not set bit 2 in printmask, a misleading message may result if the actual hardware, firmware, or patch levels were updated without a corresponding change to the diagnostic's expected revision levels.

3. Known Bugs and Deficiencies: The console command language uses the device names CSA1 and CSA2 for the console floppy drives. The Supervisor,however,always refers to either drive as CSA0.

RELEASE NOTES FOR
VAX-11 DIAGNOSTIC SUPERVISOR
VERSION 9.2
March 25,1986

1. EZSAA-9.2-292

   - The p-table for the KA850 has been added .

   - This version has support code for attaching the floppies, CSA1,CSA2 and the winchester RD disk,CSA3. Upon boot of the supervisor the default disk will be CSA3,the winchester RD disk. I/O can be done from any of the afor-mentioned devices after doing a SET LOAD to that particular device.

RELEASE NOTES FOR
VAX-11 DIAGNOSTIC SUPERVISOR
VERSION 9.3
April 4,1986

1. EZSAA-9.3-305

   o This version has support for the DMB32

RELEASE NOTES FOR
VAX-11 DIAGNOSTIC SUPERVISOR
VERSION 10.0
April 30, 1986

1 ENHANCEMENTS

This version, 10.0, contains only the 8200/8300 supervisor. Support includes booting the supervisor on the attached processor, running of multiprocessor diagnostics, and new BI adapters.

1.1 New BI Adapters

1. DWBLA - This adapter is a combination of a DWBUA and LESI controller. TU81 tape drives and RC25/RC25F disk drives are connected to it. Note that the TU81 is attached directly to the DWBLA, while the RC25 and RCF25 must be attached to a LESI which in turn must be attached to the DWBLA. They are attached as follows:

```
DS>
DS> ATTACH DWBLA HUB BLA0 ! BLA adapter
BI Node Number (HEX) ? 6
DS>
DS> ATTACH TU81 BLA0 MUA0 ! TU81 tape drive
CSR? 774500
VECTOR? 260
BR? 5
DS>
DS> ATTACH LESI BLA0 DAA  ! LESI controller (part of the DWBLA)
IP? 774500
Vector? 260
BR? 5
DS>
DS> ATTACH RC25 DAA DAA0  ! AZTEC removable disk drive
DS> ATTACH RCF25 DAA DAA1 ! AZTEC fixed head disk drive
DS>
```

2. DMB32 - This is a synchronous/asynchronous multiplexer. It is attached as follows:

```
DS> ATTACH DMB32 HUB TXA  ! DMB32 adapter
BI Node Number (HEX)? 3
DS>
```

1.2 New Features For The 8300 Systems.

o Attached processor (AP) support. Allows running the VDS on the AP. A new command, BOOT node (where node = node number of AP), allows the Supervisor to execute on the AP. The primary processor (PP) continues to run in order to provide console I/O (both terminal and floppy), but it does not execute any diagnostics. The Supervisor operates on the AP as it would on the PP. To return control to the PP, use the EXIT command. WARNING: Before any transition between the AP and the PP, ensure that the diagnostic has completed or has been ABORTed.

EXAMPLE of running the VDS on an AP (node F):

```

o VAX Diagnostic Supervisor support for multi-processor diagnostics.

  * Multiprocessor Concepts:

    A few diagnostic programs are designed to run concurrently on multiple processors. In a multiprocessing environment, you boot the VDS in one of the processors. The processor running the VDS is called the primary processor. If you load and start a multiprocessing diagnostic program, it will cause one or more of the other processors to execute code simultaneously with the primary processor. These other processors are called attached processors. New services have been added to the VAX Diagnostic Supervisor to support multi-processor diagnostics.

  * VDS in a Multiprocessor Environment:

    This section describes the VDS features that facilitate the execution of diagnostic programs on multiprocessor systems.

    General Concepts

    In a multiprocessor environment, the processor used to boot the VDS is called the "primary processor". All other processors are called "attached processors". Labeling processors as primary and attached is just a software definition and does not imply any particular hardware configuration. "Attached" processors bear no

relation to the VDS ATTACH command.

When the VDS is booted, it always assumes there is only one processor.

When operating on a multiprocessor system, there is one copy of the VDS software. Control portions of the VDS, such as the command line interpreter and the command dispatcher, are executed only by the primary processor. Some portions of the code, such as system services and exception handlers, may be executed by any processor.

It is assumed that a common memory is shared by all processors.

Diagnostic programs are loaded by and initially executed by the primary processor. A diagnostic program may consist of one or more secondary portions that can be executed by one or more attached processors. In this document, the code executing in the primary processor is referred to as the "primary process". Code executing in an attached processor is called an "attached process".

* Attaching and Selecting Attached Processors:

If a diagnostic program is to use more than one processor, ATTACH commands must be used to describe each processor. You specify which processors to test by ATTACHing and SELECTing them. The diagnostic program calls the $DS_GPHARD service to find out which processors to use.

* Multiprocessing Macros:

The VDS provides the following system services for use in multiprocessor environments:

- $DS_BOOTATTACHED boots an attached processor and leaves the processor in an execution loop called an "idle loop", which is a "JMP" instruction.

- $DS_BGNATTACHED and $DS_ENDATTACHED delineate the code to be executed in an attached processor.

- $DS_STARTATTACHED causes an attached processor to begin executing at a specified address. The code to be executed must be delimited by the $DS_BGNATTACHED and $_ENDATTACHED macros. When execution of this code is complete, the processor is automatically returned to its idle loop.

- $DS_HALTATTACHED halts an attached processor.

- $DS_SHOWIDLE indicates which attached processors are currently executing "idle loops".

- A new value for the $DS_EXIT argument, ATTACHED, lets you exit from the currently attached process. You must locate the $DS_EXIT macro between the $DS_BGNATTACHED and $DS_ENDATTACHED macros.

* Executing in an Attached Processor:

In order for a diagnostic program to execute an attached process, the following steps must occur:

- The attached processor must be booted using the $DS_BOOTATTACHED service.

- The code to be executed must be loaded either by including the code within the source file of the code executing in the primary or by including it in a separate file. If you use a separate file, you must:

  a Call the $DS_GETBUF service to allocate memory space for the attached process.

  a Use the $DS_LOAD service or RMS services to load the file into the space assigned by the $DS_GETBUF service.

- The $DS_STARTATTACHED service passes the attached processor the address where the code begins. In the case where the attached process is loaded into a buffer, the address is the same as the buffer itself.

- The attached process begin executing; VDS system services may be called.

You must repeat the process for each attached processor.

* Using System Services;

Most system services may be called from code executing in attached processors. These services provide an interlocking mechanism, transparent to the diagnostic program, that assures that only one processor executes the service routine at a time. If two or more processors often issue calls to the same service, a large amount of system time may be spent waiting for one processor to finish with the service so that the other one can use it. If two or more processors are locked out of a service because it is in use, the next processor to be serviced is completely arbitrary, as there is no enqueueing of service requests.

The following services may not be called from code

executing in an attached processor:

$DS_ASKxxxx

$DS_CHANNEL

$DS_CLRVEC

$DS_ERRxxx

$DS_INITSCB

$DS_LOAD

$DS_MMON, $DS_MMOFF

$DS_PARSE

$DS_PRINTx

$DS_SETMAP

$SETIMR

$DS_SETVEC

$DS_WAITMS

Additionally, the $DS_MMON and $DS_MMOFF may not be called from code executing in the primary processor after an attached processor has been booted (with the $DS_BOOTATTACHED service).

* Memory Management:

Memory mapping for all processors is identical. Any code within the VDS that alters the page tables alters the tables for each processor because there is one set of page tables for all processors. Page table base registers for each processor simply point to the same places.

However, consider the following scenario:

- You run a diagnostic program that creates attached processes.
- Execution of the diagnostic program is stopped by control-C, a breakpoint, or an exception condition.
- You issue either a SET MM ON or SET MM OFF command and then issue the CONTINUE command.

In this scenario, the state of memory management in the primary processor changes when you issue the SET MM

command. The state of memory management in the attached processors, however, does not change until you issue the CONTINUE command.

If each processor executes $DS_GETBUF macros, $DS_RELBUF cannot be used to separately release buffers allocated to each processor because $DS_RELBUF deallocates the last allocated blocks no matter who requested them. All $DS_GETBUF and $DS_RELBUF calls should be made by the primary process. Alternately, you can use a globally-referenced location to track total buffer allocation. Then you can issue one $DS_RELBUF call to deallocate all allocated space at once.

* Timing:

The only timing service available is the $DS_WAITUS. Any other timing scheme must be designed by the user.

It is important to note that only one $DS_WAITUS request may be serviced at any time. If one processor, for example, requests a $DS_WAITUS service and the $DS_WAITUS service routine is already in use by another processor, the requesting processor is forced (by the VDS) to wait until the service routine has completed its execution for the first processor.

The result will be that the actual amount of time the second processor has to wait could be considerably longer than the actual wait time requested. Be aware that if more than one processor is waiting for service, it is arbitrary as to which is serviced first, as there is no enqueueing of requests.

* The SCB:

Each processor has its own SCB that is initialized when the processor is bootstrapped. All SCBs are initialized as follows:

- All vectors in the first half page of the SCB point to the proper exception handlers. Note that all handlers are the same for each processor.

- The rest of the SCB (the device interrupt vector area) points to the VDS's unexpected interrupt handler. Only the primary processor, however, receives device interrupts (See the section entitled, "Input/Output").

The $DS_SETVEC, $DS_CLRVEC, and $DS_INITSCB services can only be called by the primary process. If an attached process wants to modify its SCB, it must do so directly. The SCB base address is returned by the $DS_BOOTATTACHED service.

* Input/Output:

  Only the primary processor may receive device interrupts. (For some processor types, this is a hardware restriction, for others, it is not. For consistency's sake, VDS implementation is the same for all processor types.)

  The $DS_CHANNEL service may be called only by the primary processor.

  Device interrupt service routines only execute in the primary processor and are considered a part of the main program. The main program may notify an attached process that an interrupt has been received by setting an event flag or by delivering an interprocessor interrupt to the attached processor.

  It is important to remember that the $DS_CHANNEL service only allows one device interrupt service routine in use at a time. Therefore if several devices are to be active at once, they must all be serviced by the same interrupt service routine. (The routine can determine which device caused the most recent interrupt, since the vector address is passed to the routine.)

* ASTs:

  Only the primary processor can execute a service that provides AST delivery. (These services, for level 3 programs, include $SETIMR, $DS_CNTRLC, and, indirectly, $DS_WAITMS.) AST requests from all processors are enqueued into a common AST queue.

* Interprocessor Interrupts:

  Diagnostic programs may implement interprocessor communication by using interprocessor interrupts. Diagnostic programs wishing to make use of interprocessor interrupts may modify the SCBs of the various processors so that the IP interrupt vector points to an interrupt service routine specified by the program.

  The VDS does not use interprocessor interrupts.

* Exceptions and Unexpected Interrupts:

  The SCB of each processor is initialized so that exceptions vector into VDS condition handlers that provide interlocking. The last chance handler stops program execution on all processors, no matter which processor "trapped out". The primary processor re-enters VDS CLI and issues the DS> prompt. All attached processors re-enter their idle loops.

Diagnostic programs can override the VDS last chance handler by specifying their own condition handlers.

Unexpected device interrupts are fielded by the primary processor. The primary processor's unexpected interrupt handler reports the interrupt to the user and re-enters VDS CLI, issuing the DS> prompt. All attached processors are forced to re-enter their idle loops.

* Control-Cs:

You can return to the VDS CLI and the DS> prompt by typing control-C. Attached processors return to their idle loops the next time they call the $DS_BREAK service.

As is currently the case, a diagnostic program may declare its own control-C handler to take precedence over the VDS control-C handler.

* Communication Between the Main and Attached Processes:

Since the VDS does not provide specific services to facilitate communication between the attached processes and the primary process, you can use any of the following techniques:

- o Event Flags - Very useful for passing status information between the primary and various attached processes. The $SETEF, $CLREF, $READEF, $WAITFR, $WFLAND, and $WFLOR services may all be used by any process.

- o Interprocessor Interrupts - Available for use by the diagnostic program; you may design any scheme you wish for making use of interprocessor interrupts.

- o Common "mailbox" - You can specify a common data area in which to pass information back and forth between the main process and the attached processes.

- o Dispatch vectors - Attached processes can call routines in the main process via dispatch vectors, stored in a table in the main process, that point to the routines. If these vectors are assigned to absolute addresses, then attached processes not linked with the main process can reference them. (If the code for attached processes is linked with the main process, dispatch vectors are unnecessary, since addressing references may be relative and can be resolved at link time.)

* Restrictions:

The following restrictions apply to diagnostic programs using the multiprocessing features of the VDS:

- As with single processor systems, code executing in attached processors must periodically call the $DS_BREAK service. THIS RULE IS VERY IMPORTANT, as breakpoints, control-C's, and exception handling depend upon this rule being followed.

- With the exception of $DS_BGNATTACHED and $DS_ENDATTACHED, code executing in attached processors may not use any of the program structure macros. (These macros include $DS_BGNTEST, $DS_ENDTEST, $DS_BGNSUB, $DS_ENDSUB, and the macros $DS_HEADER and $DS_DISPATCH that define such data structures as the diagnostic header and the dispatch table, respectively.) All initialization and clean-up code, looping, and error reporting must be contained within code executed by the primary processor.

- The load image for a diagnostic program may not be larger than approximately 63.5 Kbytes. If the total size of the code to be executed by the primary and all attached processes exceeds the maximum, you have to store the code for attached processors in separate loadable images. (Refer to the section entitled "Executing in an Attached Processor".)

- As stated previously, requests for system services are not enqueued (except in the case of ASTs). Therefore if several attached processes are simultaneously requesting the same service, there is no way to determine which process will be serviced next. It is assumed (but not guaranteed by the software) that all requests will eventually be serviced. All services have an interlocking mechanism, so that the next processor to execute the service is the first one to reference the interlocking flag after the service is released (by the previous processor.)

- Only the primary processor can receive device interrupts.

- Use the standard methods for declaring condition handlers.

- All multi-processor diagnostics must run in Kernel mode.

- It is recommended that the diagnostic clean-up code call the $DS_HALTATTACHED service in order that each Attached Processor that was bootattached be placed in a known, static state.

- Code executing in an attached processor may not call the following services:

  $DS_ASKxxxx
  $DS_CHANNEL
  $DS_CLRVEC
  $DS_ERRxxx
  $DS_INITSCB
  $DS_LOAD
  $DS_MMON, $DS_MMOFF
  $DS_PARSE
  $DS_PRINTx
  $DS_SETVEC
  $SETIMR
  $DS_SETMAP
  $DS_WAITMS

* Multi-processor Macros:

  - $DS_BGNATTACHED, $DS_ENDATTACHED

    In a diagnostic program that tests multiple processors, use the $DS_BGNATTACHED and $DS_ENDATTACHED macros to delineate code that is to be executed in an attached processor. These macros are used whether the code is included in the loadable image of the main diagnostic program or it is a separate loadable image.

    $DS_BGNATTACHED indicates the beginning of the code and creates a label that can be used with the $DS_STARTATTACHED service. The $DS_ENDATTACHED macro generates code that will send the processor back to its idle loop.

    MACRO-32 Format:

```
$DS_BGNATTACHED routine_name, mask
        .
        .
        .
$DS_ENDATTACHED
```

    BLISS-32 Format:

```
$DS_BGNATTACHED (ROUTINE_NAME=routine_name);
        .
        .
        .
$DS_ENDATTACHED;
```

    routine_name

    Labels the routine and points to its first instruction.

mask
List of register names used in the entry mask.

Notes:

1. You can include code that is contained in an attached process in any number of separate executable files. The code in each file, however, must be position-independent. You can only have one attached process, delimited by one set of $DS_BGNATTACHED and $DS_ENDATTACHED macros, per file.

2. If you want to place the code in a separate image, request a buffer using the $DS_GETBUF service, load the image into the buffer, and use the address of the buffer as the "start_addr" argument for the $DS_STARTATTACHED macro.

3. You can enter the code using a CALL instruction.

4. It is recommended that you place data structures for the code in a separate psect. If you must include the data structures

   in the same psect as the code, place them (data structures) after the code and end the executable section with a $DS_EXIT macro as shown:

```
.psect data                 $DS_BGNATTACHED RTN2
        .                           .
<data structures>                   .
        .                   <executable code>
        .                           .
.psect code                         .
$DS_BGNATTACHED RTN1        $DS_EXIT ATTACHED
        .                           .
        .                           .
<executable code>           <data structures>
        .                           .
        .                           .
        .
$DS_ENDATTACHED             $DS_ENDATTACHED
```

o $DS_BOOTATTACHED

In a multiprocessing environment, use the Boot Attached CPU system service to bootstrap an attached processor on a multiprocessor system. It will perform the following functions for the target processor:

1. Halt the processor, if it is not currently halted.

2. Perform all initialization necessary to enable the processor to execute code, including initializing stacks, memory management registers, the SCB, and the interval clock.

3. Cause the processor to begin executing an idle loop ("JMP ." instruction).

After you call the $DS_BOOTATTACHED, you can use the $DS_STARTATTACHED service to cause the attached processor to leave its idle loop and begin executing a section of code.

MACRO-32 Format:

```
$DS_BOOTATTACHED_x unit, scb_addr
```

BLISS-32 Format:

```
$DS_BOOTATTACHED (UNIT=unit, SCB_ADDR=scb_addr);
```

unit

Logical unit number of the processor to be bootstrapped.

scb_addr

Address of the longword to receive the SCB address of the target processor.

Return Status:

DS$_NORMAL

Service successfully completed.

DS$_ILLUNIT

The specified logical unit number is too large.

DS$_INVCPU

Can't boot specified processor.

DS$_MEM_ALLOC_ERR

Could not allocate memory for attached processor's SCB and stacks.

DS$_INIT_FAIL
Attached processor did not return prompt from Control P or Initialize. (VAX 8200 only)

Examples:

MACRO-32 Example:

```
$DS_BOOTATTACHED_S      LOG_UNIT, PROC2_SCB
```

BLISS-32 Example:

```
$DS_BOOTATTACHED (UNIT = .LOG_UNIT, SCB_ADDR =
                  PROC2_SCB);
```

o $DS_HALTATTACHED

Use the Halt Attached CPU system service to stop program execution in an attached processor or a multiprocessor environment. In order to use this service, you must bootstrap the processor with the $DS_BOOTATTACHED service. This service should be used in the clean-up code of a multi-processor diagnostic to place each Attached Processor that was bootattached into a known, static state.

MACRO-32 Format:

```
$DS__HALTATTACHED__x unit
```

BLISS-32 Format:

```
$DS__HALTATTACHED (UNIT=unit);
```

unit

Logical unit number of the CPU to be halted.

Return Status:

DS$_NORMAL

Service successfully completed.

DS$_ILLUNIT

The specified logical unit number is too large.

DS$_INVCPU

The specified processor is the primary processor.

DS$_INIT_FAIL

The processor failed to send console prompt only).

Notes:

1. In order to restart a halted processor, you must reboot using the $DS_BOOTATTACHED service and then use the $DS_STARTATTACHED service.

Examples:

MACRO-32 Example:

```
$DS__HALTATTACHED__S    LOG_UNIT
```

BLISS-32 Example:

```
$DS__HALTATTACHED (UNIT = .LOG_UNIT);
```

- $DS_SHOWIDLE

In a multiprocessor environment, use the Show Idle Processors service to determine which attached processors are currently executing their "idle loops". Attached processors are placed in their idle loops when:

1. The $DS_BOOTATTACHED service has completed bootstrapping the processor.

2. An attached process, delimited by the $DS_BGNATTACHED and $DS_ENDATTACHED macros, finishes executing.

3. A multiprocessor diagnostic program is stopped by a control-C or an exception.

MACRO-32 Format:

```
$DS_SHOWIDLE_x  bitmap
```

BLISS-32 Format:

```
$DS_SHOWIDLE (BITMAP=bitmap);
```

bitmap

Address of the longword to receive a bitmap indicating which attached processors are currently executing their idle loops. There are 32 bits (0 through 31); each bit corresponding to a logical unit number. You need to look at the bits that correspond

to logical unit numbers actually associated with attached processors. (See Note 1.)

Return Status:

DS$_NORMAL

Service successfully completed.

Notes:

1. One method for using this service is to create a bit mask. Each time you issue a $DS_GPHARD call and receive the address of a p-table for an attached processor, set the bit in the mask corresponding to the logical unit number for that p-table. When you call the $DS_SHOWIDLE service, test only the bits that are set in the mask you created.

Examples:

MACRO-32 Example:

```
IDLE_MASK:      .LONG 0
IDLE_PROC:      .LONG 0

                .
                .
        $DS_SHOWIDLE_S (IDLE_PROC)  ; Get idling
                                    ; processors.
        CMPL    IDLE_MASK,IDLE_PROC ; All idling?
        BEQL    300$                ; Yes, branch.
                .
                .
```

BLISS-32 Example:

```
                .
                .
        $DS_SHOWIDLE (BITMAP=IDLE_PROC); ! Get idling
                                         ! processors.
        IF (.IDLE_MASK NEQ .IDLE_PROC)   ! If not idling
        THEN                             ! then...
                .
                .
```

o $DS_STARTATTACHED

In a multiprocessor environment, you can use the Start Attached CPU system service to cause an attached processor to begin executing a section of code. Before you can use this service, you must bootstrap the specified processor with the $DS_BOOTATTACHED service.

You must delimit the section of code to be executed with the $DS_BGNATTACHED and $DS_ENDATTACHED program structure macros. The service, in conjunction with these macros, causes the specified processor to leave the idle loop that was created by the $DS_BOOTATTACHED service and jump to the code delimited by the macros. When it finishes executing, the processor re-enters the idle loop. (Refer to the description of the $DS_BGNATTACHED and $DS_ENDATTACHED macros for details.)

MACRO-32 Format:

```
$DS_STARTATTACHED_x unit, start_addr
```

BLISS-32 Format:

```
$DS_STARTATTACHED (UNIT=unit, START_ADDR=start_addr);
```

unit

Logical unit number of the processor to be bootstrapped.

start_addr

Address of the code to be executed in the attached processor. This argument must be the address of the code generated by a $DS_BGNATTACHED macro.

Return Status:

DS$_NORMAL

Service successfully completed.

DS$_ILLUNIT

The specified logical unit number is too large.

DS$_INVCPU

Can't start the specified processor. May mean the processor doesn't exist or the processor was not executing its idle loop (see $DS_BOOTATTACHED).

Examples:

MACRO-32 Example:

```
.
.
.
```

```
            $DS_BGNATTACHED ROUTINE1
                    .
                    .
                    .
            $DS_ENDATTACHED
                    .
                    .
                    .
            $DS_STARTATTACHED_S     LOG_UNIT, ROUTINE1
        BLISS-32 Example:
                    .
                    .
                    .
            $DS_BGNATTACHED (ROUTINE_NAME=ROUTINE1);
                    .
                    .
                    .
            $DS_ENDATTACHED;
                    .
                    .
                    .
            $DS_STARTATTACHED (UNIT = .LOG_UNIT,
                               START_ADDR=ROUTINE1);
```

2 KNOWN BUGS AND DEFICIENCIES

1. Version 9.0 has a bug whereby depositing into an Internal Processor Register at the Diagnostic Supervisor prompt will yield incorrect results. Version 10.0 fixes this problem.

2. The bug in version 9.0 which prevented the diagnostic supervisor from being booted from a CIBCI disk has been fixed. Previously a machine check would result.

3. In version 9.0, the supervisor was inadvertently clearing the BROKE bit for memory adapters at boot time, if the adapter had previously set the BROKE bit. This has been fixed.

4. In version 9.0, after an ULTRIX system had previously been running, an "Unexpected BI bus error interrupt" would occur while running EBUCA. This has been fixed.

RELEASE NOTES FOR
VAX-11 DIAGNOSTIC SUPERVISOR
VERSION 10.1
April 4, 1986

1 ENHANCEMENTS

This version, 10.1, contains only the 8500/8700/8800 supervisor. Support includes running of multiprocessor diagnostics.

1.1 Multiprocessing

- VAX Diagnostic Supervisor support for multi-processor diagnostics.

  * Multiprocessor Concepts:

    A few diagnostic programs are designed to run concurrently on multiple processors. In a multiprocessing environment, you boot the VDS in one of the processors. The processor running the VDS is called the primary processor. If you load and start a multiprocessing diagnostic program, it will cause one or more of the other processors to execute code simultaneously with the primary processor. These other processors are called attached processors. New services have been added to the VAX Diagnostic Supervisor to support multi-processor diagnostics.

* VDS in a Multiprocessor Environment:

  This section describes the VDS features that facilitate the execution of diagnostic programs on multiprocessor systems.

  General Concepts

  In a multiprocessor environment, the processor used to boot the VDS is called the "primary processor". All other processors are called "attached processors". Labeling processors as primary and attached is just a software definition and does not imply any particular hardware configuration. "Attached" processors bear no relation to the VDS ATTACH command.

  When the VDS is booted, it always assumes there is only one processor.

When operating on a multiprocessor system, there is one copy of the VDS software. Control portions of the VDS, such as the command line interpreter and the command dispatcher, are executed only by the primary processor. Some portions of the code, such as system services and exception handlers, may be executed by any processor.

It is assumed that a common memory is shared by all processors.

Diagnostic programs are loaded by and initially executed by the primary processor. A diagnostic program may consist of one or more secondary portions that can be executed by one or more attached processors. In this document, the code executing in the primary processor is referred to as the "primary process". Code executing in an attached processor is called an "attached process".

* Attaching and Selecting Attached Processors:

If a diagnostic program is to use more than one processor, ATTACH commands must be used to describe each processor. You specify which processors to test by ATTACHing and SELECTing them. The diagnostic program calls the $DS_GPHARD service to find out which processors to use.

* Multiprocessing Macros:

The VDS provides the following system services for use in multiprocessor environments:

- $DS_BOOTATTACHED boots an attached processor and leaves the processor in an execution loop called an "idle loop", which is a "JMP" instruction.

- $DS_BGNATTACHED and $DS_ENDATTACHED delineate the code to be executed in an attached processor.

- $DS_STARTATTACHED causes an attached processor to begin executing at a specified address. The code to be executed must be delimited by the $DS_BGNATTACHED and $_ENDATTACHED macros. When execution of this code is complete, the processor is automatically returned to its idle loop.

- $DS_HALTATTACHED halts an attached processor.

- $DS_SHOWIDLE indicates which attached processors are currently executing "idle loops".

- A new value for the $DS_EXIT argument, ATTACHED, lets you exit from the currently attached process. You must locate the $DS_EXIT macro between the $DS_BGNATTACHED and $DS_ENDATTACHED macros.

* Executing in an Attached Processor:

  In order for a diagnostic program to execute an attached process, the following steps must occur:

  - The attached processor must be booted using the $DS_BOOTATTACHED service.
  - The code to be executed must be loaded either by including the code within the source file of the code executing in the primary or by including it in a separate file. If you use a separate file, you must:
    - Call the $DS_GETBUF service to allocate memory space for the attached process.
    - Use the $DS_LOAD service or RMS services to load the file into the space assigned by the $DS_GETBUF service.
  - The $DS_STARTATTACHED service passes the attached processor the address where the code begins. In the case where the attached process is loaded into a buffer, the address is the same as the buffer itself.
  - The attached process begin executing; VDS system services may be called.

  You must repeat the process for each attached processor.

* Using System Services;

  Most system services may be called from code executing in attached processors. These services provide an interlocking mechanism, transparent to the diagnostic program, that assures that only one processor executes the service routine at a time. If two or more processors often issue calls to the same service, a large amount of system time may be spent waiting for one processor to finish with the service so that the other one can use it. If two or more processors are locked out of a service because it is in use, the next processor to be serviced is completely arbitrary, as there is no enqueueing of service requests.

  The following services may not be called from code executing in an attached processor:

  $DS_ASKxxxx

  $DS_CHANNEL

$DS_CLRVEC

$DS_ERRxxx

$DS_INITSCB

$DS_LOAD

$DS_MMON, $DS_MMOFF

$DS_PARSE

$DS_PRINTx

$DS_SETMAP

$SETIMR

$DS_SETVEC

$DS_WAITMS

Additionally, the $DS_MMON and $DS_MMOFF may not be called from code executing in the primary processor after an attached processor has been booted (with the $DS_BOOTATTACHED service).

* Memory Management:

Memory mapping for all processors is identical. Any code within the VDS that alters the page tables alters the tables for each processor because there is one set of page tables for all processors. Page table base registers for each processor simply point to the same places.

However, consider the following scenario:

o You run a diagnostic program that creates attached processes.

o Execution of the diagnostic program is stopped by control-C, a breakpoint, or an exception condition.

o You issue either a SET MM ON or SET MM OFF command and then issue the CONTINUE command.

In this scenario, the state of memory management in the primary processor changes when you issue the SET MM command. The state of memory management in the attached processors, however, does not change until you issue the CONTINUE command.

If each processor executes $DS_GETBUF macros, $DS_RELBUF cannot be used to separately release buffers allocated to

each processor because $DS_RELBUF deallocates the last allocated blocks no matter who requested them. All $DS_GETBUF and $DS_RELBUF calls should be made by the primary process. Alternately, you can use a globally-referenced location to track total buffer allocation. Then you can issue one $DS_RELBUF call to deallocate all allocated space at once.

* Timing:

  The only timing service available to an Attached Processor is the $DS_WAITUS. Any other timing scheme must be designed by the user.

  It is important to note that only one $DS_WAITUS request may be serviced at any time. If one processor, for example, requests a $DS_WAITUS service and the $DS_WAITUS service routine is already in use by another processor, the requesting processor is forced (by the VDS) to wait until the service routine has completed its execution for the first processor.

  The result will be that the actual amount of time the second processor has to wait could be considerably longer than the actual wait time requested. Be aware that if more than one processor is waiting for service, it is arbitrary as to which is serviced first, as there is no enqueueing of requests.

* The SCB:

  Each processor has its own SCB that is initialized when the processor is bootstrapped. All SCBs are initialized as follows:

  o All vectors in the first half page of the SCB point to the proper exception handlers. Note that all handlers are the same for each processor.

  o The rest of the SCB (the device interrupt vector area) points to the VDS's unexpected interrupt handler. Only the primary processor, however, receives device interrupts (See the section entitled, "Input/Output").

  The $DS_SETVEC, $DS_CLRVEC, and $DS_INITSCB services can only be called by the primary process. If an attached process wants to modify its SCB, it must do so directly. The SCB base address is returned by the $DS_BOOTATTACHED service.

* Input/Output:

Only the primary processor may receive device interrupts. (For some processor types, this is a hardware restriction, for others, it is not. For consistency's sake, VDS implementation is the same for all processor types.)

The $DS_CHANNEL service may be called only by the primary processor.

Device interrupt service routines only execute in the primary processor and are considered a part of the main program. The main program may notify an attached process that an interrupt has been received by setting an event flag or by delivering an interprocessor interrupt to the attached processor.

It is important to remember that the $DS_CHANNEL service only allows one device interrupt service routine in use at a time. Therefore if several devices are to be active at once, they must all be serviced by the same interrupt service routine. (The routine can determine which device caused the most recent interrupt, since the vector address is passed to the routine.)

* ASTs:

Only the primary processor can execute a service that provides AST delivery. (These services, for level 3 programs, include $SETIMR, $DS_CNTRLC, and, indirectly, $DS_WAITMS.) AST requests from all processors are enqueued into a common AST queue.

* Interprocessor Interrupts:

Diagnostic programs may implement interprocessor communication by using interprocessor interrupts. Diagnostic programs wishing to make use of interprocessor interrupts may modify the SCBs of the various processors so that the IP interrupt vector points to an interrupt service routine specified by the program.

The VDS does not use interprocessor interrupts.

* Exceptions and Unexpected Interrupts:

The SCB of each processor is initialized so that exceptions vector into VDS condition handlers that provide interlocking. The last chance handler stops program execution on all processors, no matter which processor "trapped out". The primary processor re-enters VDS CLI and issues the DS> prompt. All attached processors re-enter their idle loops.

Diagnostic programs can override the VDS last chance handler by specifying their own condition handlers.

Unexpected device interrupts are fielded by the primary processor. The primary processor's unexpected interrupt handler reports the interrupt to the user and re-enters VDS CLI, issuing the DS> prompt. All attached processors are forced to re-enter their idle loops.

* Control-Cs:

  You can return to the VDS CLI and the DS> prompt by typing control-C. Attached processors return to their idle loops the next time they call the $DS_BREAK service.

  As is currently the case, a diagnostic program may declare its own control-C handler to take precedence over the VDS control-C handler.

* Communication Between the Main and Attached Processes:

  Since the VDS does not provide specific services to facilitate communication between the attached processes and the primary process, you can use any of the following techniques:

  - Event Flags - Very useful for passing status information between the primary and various attached processes. The $SETEF, $CLREF, $READEF, $WAITFR, $WFLAND, and $WFLOR services may all be used by any process.

  - Interprocessor Interrupts - Available for use by the diagnostic program; you may design any scheme you wish for making use of interprocessor interrupts.

  - Common "mailbox" - You can specify a common data area in which to pass information back and forth between the main process and the attached processes.

  - Dispatch vectors - Attached processes can call routines in the main process via dispatch vectors, stored in a table in the main process, that point to the routines. If these vectors are assigned to absolute addresses, then attached processes not linked with the main process can reference them. (If the code for attached processes is linked with the main process, dispatch vectors are unnecessary, since addressing references may be relative and can be resolved at link time.)

* Restrictions:

  The following restrictions apply to diagnostic programs using the multiprocessing features of the VDS:

- As with single processor systems, code executing in attached processors must periodically call the $DS_BREAK service. THIS RULE IS VERY IMPORTANT, as breakpoints, control-C's, and exception handling depend upon this rule being followed.

- With the exception of $DS_BGNATTACHED and $DS_ENDATTACHED, code executing in attached processors may not use any of the program structure macros. (These macros include $DS_BGNTEST, $DS_ENDTEST, $DS_BGNSUB, $DS_ENDSUB, and the macros $DS_HEADER and $DS_DISPATCH that define such data structures as the diagnostic header and the dispatch table, respectively.) All initialization and clean-up code, looping, and error reporting must be contained within code executed by the primary processor.

- The load image for a diagnostic program may not be larger than approximately 63.5 Kbytes. If the total size of the code to be executed by the primary and all attached processes exceeds the maximum, you have to store the code for attached processors in separate loadable images. (Refer to the section entitled "Executing in an Attached Processor".)

- As stated previously, requests for system services are not enqueued (except in the case of ASTs). Therefore if several attached processes are simultaneously requesting the same service, there is no way to determine which process will be serviced next. It is assumed (but not guaranteed by the software) that all requests will eventually be serviced. All services have an interlocking mechanism, so that the next processor to execute the service is the first one to reference the interlocking flag after the service is released (by the previous processor.)

- Only the primary processor can receive device interrupts.

- Use the standard methods for declaring condition handlers.

- All multi-processor diagnostics must run in Kernel mode.

- It is recommended that the diagnostic clean-up code call the $DS_HALTATTACHED service in order that each Attached Processor that was bootattached be placed in a known, static state.

- Code executing in an attached processor may not call the following services:

  $DS_ASKxxxx
  $DS_CHANNEL
  $DS_CLRVEC
  $DS_ERRxxx
  $DS_INITSCB
  $DS_LOAD
  $DS_MMON, $DS_MMOFF
  $DS_PARSE
  $DS_PRINTx
  $DS_SETVEC
  $SETIMR
  $DS_SETMAP
  $DS_WAITMS

* Multi-processor Macros:

  - $DS_BGNATTACHED, $DS_ENDATTACHED

    In a diagnostic program that tests multiple processors, use the $DS_BGNATTACHED and $DS_ENDATTACHED macros to delineate code that is to be executed in an attached processor. These macros are used whether the code is included in the loadable image of the main diagnostic program or it is a separate loadable image.

    $DS_BGNATTACHED indicates the beginning of the code and creates a label that can be used with the $DS_STARTATTACHED service. The $DS_ENDATTACHED macro generates code that will send the processor back to its idle loop.

    MACRO-32 Format:

```
$DS_BGNATTACHED routine_name, mask
        .
        .
        .
$DS_ENDATTACHED
```

    BLISS-32 Format:

```
$DS_BGNATTACHED (ROUTINE_NAME=routine_name);
        .
        .
        .
$DS_ENDATTACHED;
```

routine_name

Labels the routine and points to its first instruction.

mask

List of register names used in the entry mask.

Notes:

1. You can include code that is contained in an attached process in any number of separate executable files. The code in each file, however, must be position-independent. You can only have one attached process, delimited by one set of $DS_BGNATTACHED and $DS_ENDATTACHED macros, per file.

2. If you want to place the code in a separate image, request a buffer using the $DS_GETBUF service, load the image into the buffer, and use the address of the buffer as the "start_addr" argument for the $DS_STARTATTACHED macro.

3. You can enter the code using a CALL instruction.

4. It is recommended that you place data structures for the code in a separate psect. If you must include the data structures

   in the same psect as the code, place them (data structures) after the code and end the executable section with a $DS_EXIT macro as shown:

```
.psect data                 $DS_BGNATTACHED RTN2
        .                           .
<data structures>                   .
        .                   <executable code>
        .                           .
.psect code                         .
$DS_BGNATTACHED RTN1        $DS_EXIT ATTACHED
        .                           .
        .                           .
<executable code>           <data structures>
        .                           .
        .                           .
$DS_ENDATTACHED             $DS_ENDATTACHED
```

- $DS_BOOTATTACHED

In a multiprocessing environment, use the Boot Attached CPU system service to bootstrap an attached processor on a multiprocessor system. It will perform the following functions for the target processor:

1. Halt the processor, if it is not currently halted.

2. Perform all initialization necessary to enable the processor to execute code, including initializing stacks, memory management registers, the SCB, and the interval clock.

3. Cause the processor to begin executing an idle loop ("JMP ." instruction).

After you call the $DS_BOOTATTACHED, you can use the $DS_STARTATTACHED service to cause the attached processor to leave its idle loop and begin executing a section of code.

MACRO-32 Format:

```
$DS_BOOTATTACHED_x unit, scb_addr
```

BLISS-32 Format:

```
$DS_BOOTATTACHED (UNIT=unit, SCB_ADDR=scb_addr);
```

unit

Logical unit number of the processor to be bootstrapped.

scb_addr

Address of the longword to receive the SCB address of the target processor.

Return Status:

DS$_NORMAL

Service successfully completed.

DS$_ILLUNIT

The specified logical unit number is too large.

DS$_INVCPU

Can't boot specified processor.

DS$_MEM_ALLOC_ERR

Could not allocate memory for attached processor's SCB and stacks.

DS$_INIT_FAIL
Attached processor did not return prompt from Control P or Initialize. (VAX 8200 only)

Examples:

MACRO-32 Example:

```
$DS_BOOTATTACHED_S      LOG_UNIT, PROC2_SCB
```

BLISS-32 Example:

```
$DS_BOOTATTACHED (UNIT = .LOG_UNIT, SCB_ADDR =
                  PROC2_SCB);
```

o $DS_HALTATTACHED

Use the Halt Attached CPU system service to stop program execution in an attached processor or a multiprocessor environment. In order to use this service, you must bootstrap the processor with the $DS_BOOTATTACHED service. This service should be used in the clean-up code of a multi-processor diagnostic to place each Attached Processor that was bootattached into a known, static state.

MACRO-32 Format:

```
$DS__HALTATTACHED__x unit
```

BLISS-32 Format:

```
$DS__HALTATTACHED (UNIT=unit);
```

unit

Logical unit number of the CPU to be halted.

Return Status:

DS$_NORMAL

Service successfully completed.

DS$_ILLUNIT

The specified logical unit number is too large.

DS$_INVCPU

The specified processor is the primary processor.

DS$_INIT_FAIL

The processor failed to send console prompt
only).

Notes:

1. In order to restart a halted processor, you must reboot using the $DS_BOOTATTACHED service and then use the $DS_STARTATTACHED service.

Examples:

MACRO-32 Example:

```
$DS__HALTATTACHED__S    LOG_UNIT
```

BLISS-32 Example:

```
$DS__HALTATTACHED (UNIT = .LOG_UNIT);
```

- $DS_SHOWIDLE

  In a multiprocessor environment, use the Show Idle Processors service to determine which attached processors are currently executing their "idle loops". Attached processors are placed in their idle loops when:

  1. The $DS_BOOTATTACHED service has completed bootstrapping the processor.
  2. An attached process, delimited by the $DS_BGNATTACHED and $DS_ENDATTACHED macros, finishes executing.
  3. A multiprocessor diagnostic program is stopped by a control-C or an exception.

  MACRO-32 Format:

  ```
  $DS_SHOWIDLE_x  bitmap
  ```

  BLISS-32 Format:

  ```
  $DS_SHOWIDLE (BITMAP=bitmap);
  ```

  bitmap

Address of the longword to receive a bitmap indicating which attached processors are currently executing their idle loops. There are 32 bits (0 through 31); each bit corresponding to a logical unit number. You need to look at the bits that correspond to logical unit numbers actually associated with attached processors. (See Note 1.)

Return Status:

DS$_NORMAL

Service successfully completed.

Notes:

1. One method for using this service is to create a bit mask. Each time you issue a $DS_GPHARD call and receive the address of a p-table for an attached processor, set the bit in the mask corresponding to the logical unit number for that p-table. When you call the $DS_SHOWIDLE service, test only the bits that are set in the mask you created.

Examples:

MACRO-32 Example:

```
IDLE_MASK:      .LONG 0
IDLE_PROC:      .LONG 0

                .
                .
        $DS_SHOWIDLE_S (IDLE_PROC)  ; Get idling
                                    ; processors.
        CMPL    IDLE_MASK,IDLE_PROC ; All idling?
        BEQL    300$                ; Yes, branch.
                .
                .
```

BLISS-32 Example:

```
                .
                .
$DS_SHOWIDLE (BITMAP=IDLE_PROC); ! Get idling
                               ! processors.
IF (.IDLE_MASK NEQ .IDLE_PROC)  ! If not idling
THEN                            ! then...
                .
                .
```

o $DS_STARTATTACHED

In a multiprocessor environment, you can use the Start Attached CPU system service to cause an attached processor to begin executing a section of code. Before you can use this service, you must bootstrap the specified processor with the $DS_BOOTATTACHED service.

You must delimit the section of code to be executed with the $DS_BGNATTACHED and $DS_ENDATTACHED program structure macros. The service, in conjunction with these macros, causes the specified processor to leave the idle loop that was created by the $DS_BOOTATTACHED service and jump to the code delimited by the macros. When it finishes executing, the processor re-enters the idle loop. (Refer to the description of the $DS_BGNATTACHED and $DS_ENDATTACHED macros for details.)

MACRO-32 Format:

```
$DS_STARTATTACHED_x unit, start_addr
```

BLISS-32 Format:

```
$DS_STARTATTACHED (UNIT=unit, START_ADDR=start_addr);
```

unit

Logical unit number of the processor to be bootstrapped.

start_addr

Address of the code to be executed in the attached processor. This argument must be the address of the code generated by a $DS_BGNATTACHED macro.

Return Status:

DS$_NORMAL

Service successfully completed.

DS$_ILLUNIT

The specified logical unit number is too large.

DS$_INVCPU

Can't start the specified processor. May mean the processor doesn't exist or the processor was not executing its idle loop (see $DS_BOOTATTACHED).

Examples:

MACRO-32 Example:

```
        .
        .
        .
    $DS_BGNATTACHED ROUTINE1
        .
        .
        .
    $DS_ENDATTACHED
        .
        .
        .
    $DS_STARTATTACHED_S     LOG_UNIT, ROUTINE1
```

BLISS-32 Example:

```
        .
        .
        .
    $DS_BGNATTACHED (ROUTINE_NAME=ROUTINE1);
        .
        .
        .
$DS_ENDATTACHED;
        .
        .
        .
$DS_STARTATTACHED (UNIT = .LOG_UNIT,
                   START_ADDR=ROUTINE1);
```

RELEASE NOTES FOR VAX-11 DIAGNOSTIC SUPERVISOR VERSION 10.2 June 23, 1986

1 ENHANCEMENTS

* A new qualifier has been added to the START and RUN commands:

/TIME=[dddd-][hh:mm:ss.cc]

Indicates the length of time which the diagnostic program will run before execution is stopped. When the time limit expires, the diagnostic program's clean-up code is executed.

In the standalone mode, the amount of time which the program will run is the same as real time. When running under VMS, the program will run for the specified amount of cpu time rather than elapsed time.

If you also specify a number of passes to be run, the diagnostic program will stop when either the specified number of passes have been run, or the specified amount of execution time has elapsed, whichever occurs first.

If the diagnostic program's execution is interrupted by a Control-C and a CONTINUE command is typed, the diagnostic program will continue to execute for a period of time equal to the original time specified in the START or RUN command minus the time for which the diagnostic has already executed.

If the TIME qualifier is not used, or a value of zero is specified, the diagnostic program will not have a time limit placed upon its execution.

The rules for specifying a time value follow the VMS rules for specifying a delta time. The variable fields are as follows:

Field	Meaning
dddd	Number of days, 24-hour units (0 through 9999)
hh	Number of hours (0 through 23)
mm	Number of minutes (0 through 59)
ss	Number of seconds (0 through 59)
cc	Number of hundredths of seconds (0 through 99)

When you specify a time value, you can truncate the time field. You can also omit any of the variable fields, as long as you supply the punctuation marks.

When any field is omitted from a delta time value, the system supplies a value of zero for the field.

Examples:

Time Specification	Result
3-	3 days from now (72 hours)
1	1 hour from now
:20	20 minutes from now
2-:20	2 days and 20 minutes from now
::35	35 seconds from now

Notes:

1. This qualifier should not be used when the HALT flag is set, or when setting breakpoints.

2. The accuracy of this feature can be affected by the design of a diagnostic program. The diagnostic supervisor checks for an expired time limit whenever it checks for control-Cs. Since diagnostic programs are required to call a system service which checks for control-Cs at least every 3 seconds, the actual runtime should not deviate by more than 3 seconds from the desired runtime.

* Multiprocessor Enhancements

  o Breakpoints

    You can optionally set breakpoints in the code to be executed in attached processors. Whenever a breakpoint is reached by any processor, all processors are placed in their idle loops (except for the primary processor, which enters VDS command mode). Typing a CONTINUE command causes all processors to continue from the point they were stopped. Typing a NEXT command executes the next instruction only if the breakpoint was executed by the primary processor, so that you can only single step through code being executed in the primary processor.

    You can set one or more breakpoints on an Attached or Primary Processor but not both (no mixed bpt's).

    In addition, to be assured of hitting breakpoints in an Attached Processor, test code must be synchronized between the Primary and Attached CPU's such that if the Attached processor hits a breakpoint, the Primary processor would be able to report that breakpoint by

issuing periodic calls (at least every three seconds) to the $DSBREAK service.

One simple method of accomplishing this is shown in the following test structure. Of course, other methods for synchronization using the $DSBREAK service may exist.

```
Primary Processor code          Attached Processor Code
----------------------          -----------------------
    Set flag
    Start Attached Processor -----> BGNATTACHED
5$: BBC flag 10$                    Execute test code
    $DS_BREAK                                .
    BRB 5$
                                    .
                                    $DS_BREAK
                                    Clear Flag
10$: Continue                             Here the Attached could
                                    wait for another flag from
                                    the Primary to continue.
```

In this structure the attached can hit any breakpoint set between the BGNATTACHED and the clearing of the flag. The Primary processor needs to loop on $DS_BREAK to be able to report an Ap breakpoint or condition and also to respond to control-C's. A sort of stop/go flag mechanism can be designed for the Primary and Attached to execute sections of test code where the Ap can perform a test, perhaps write results, and then signal the Primary, then the primary can continue and perhaps start another section of test code. It is important that $DS_BREAK 's be called from both the Primary and Attached Processors.

When an Attached Processor hits a breakpoint, the PC of the Primary Processor (that detected the breakpoint) will point to the instruction following the $DSBREAK service that resulted in the Ap BPT message.

o Mp Diagnostic Users

If a diagnostic program not using the multiprocessor features of the VDS is executed under the new version of the VDS, the user will see no differences from current versions of the VDS. There will be two differences that a user will see when executing a program designed to run on multiple processors.

1. He/she will have to attach each processor he/she desires to be executed by the diagnostic program. However, this process is identical to the attaching sequences that are currently necessary for attaching any device before testing it.

2. In order to examine or deposit into the general purpose registers (GPRs) or internal processor registers (IPRs) of an attached processor, the user must specify the generic name of the processor (used in the ATTACH command) to indicate which processor's registers are to be examined or deposited into.

   It will not be possible to examine registers in an attached processor unless a diagnostic program has previously called the $DS_BOOTATTACHED service to boot that processor, and that attached processor has hit a breakpoint.

   A new command, SET CPU, will be added. This command will change the default processor referenced by the EXAMINE and DEPOSIT commands. For example, the command sequence

```
SET CPU KA1
EXAMINE R5
DEPOSIT R3 4
```

   will cause R5 to be examined and the value "4" to be deposited into R3 of the processor whose logical unit number is KA1.

   To keep track of which registers are being examined or deposited to, another new command called SHOW CPU has been added. Typing a SHOW CPU will indicate either PRIMARY or the generic name of the Ap used in the Attach sequence.

o Mp Restrictions

  The following restrictions apply to users of diagnostic programs which make use of the multiprocessing facilities of the VDS:

  1. It will not be possible to use the VDS EXAMINE and DEPOSIT commands to examine or deposit into the IPRs of an attached processor unless that processor has previously been booted with the $DS_BOOTATTACHED service, and that processor has hit a breakpoint.

  2. The NEXT command (single-stepping) cannot be used for code executing in an attached processor. If it is desirable to single-step the Ap, then the user should deposit a halt at the point you wish to single-step the Ap, and set a breakpoint in the Primary Processor at a convenient place, such as after calling the $DS_STARTATTACHED service. When you start the test and hit the Ap halt instruction, you can then use console commands to single-step the Ap.

3. The PC of an attached processor cannot be modified with the DEPOSIT command.

4. Only the PSW portion of the PSL in an attached processor can be examined.

5. Breakpoints can only be set for one processor at-at-time.

6. The PC will not be indicated when continuing from a multiprocessor diagnostic since more that one processor may be resuming execution of code.

2 BUG FIXES

- For 8200 systems, if the VALID bit in the WATCH chip CSR was clear (due to a bad battery, for instance), the supervisor would not boot up. Instead it would halt. This has been fixed.

- A problem with starting selftest on BI adapters on SCORPIO systems has been fixed. Previously, on some occasions, when selftest was attempted on a KDB50 adapter, a BI cycle was being truncated, resulting in ICE, RDS, or corrupted memory. This could happen to any BI adapter. The symptom was seen while running EVRLF.

3 KNOWN BUGS AND DEFICIENCIES

- If you control-C an mp diagnostic and then start and control-C a SHOW MEM command for example, the next CONTINUE command will result in a continuation of the mp diagnostic.

RELEASE NOTES FOR VAX-11 DIAGNOSTIC SUPERVISOR VERSION 10.4 December 22,1986

1 ENHANCEMENTS

* Support for logical names and search lists in USER mode

  o VMS logical names and searchlist logical names are allowed to represent file specifications. If the equivalence string of the logical name includes only part of a directory specification, it will be concatenated with the supervisor's default directory. For example, if SYS$SYSROOT is equivalent to 1DUA0:[SYS3.], and you specify SYS$SYSROOT:[SYSMAINT], the resulting filespec will be 1DUA0:[SYS3.SYSMAINT].

  o This is supported for all VDS commands and services involving file operations.

* DIRECTORY command in USER mode

  o Previous versions of VDS required that you ATTACH a device before doing a DIRECTORY of that device. It is not necessary to ATTACH the device in Version 10.4 of VDS.

* USER mode default load path

  o The VDS now sets its initial default load path to the logical name SYS$MAINTENANCE. SYS$MAINTENANCE should be defined in the system logical name table to the disk and directory which contains the system's diagnostic programs. If it is not defined, see your system manager, or define it in your process's name table.

  o In order to change the default load path, use the SET LOAD command as before. You may use DCL to define an equivalence string for SYS$MAINTENANCE in your process logical name table in order to change the VDS's initial default load path.

  o The VDS sets the default disk and directory by redefining the SYS$DISK logical name with the $CRELOG system service, and changing the default directory with the $SETDDIR service. Thus, if you attempt to SET LOAD to SYS$DISK, the VDS will redefine the logical SYS$DISK to be equivalent to itself, and file services will fail.

* Volume Shadowing

  o The VDS now supports booting and loading diagnostics from a VMS shadow set.

  o In order to boot VDS from a shadow set, R3 should be set up for VMB in the following format:

  The virtual unit number corresponds to the unit number assigned to the shadow set. The member unit can be the physical drive number of any member of the shadow set. It is used by VMB and SYSBOOT during booting in case access via the shadow set virtual number fails. The VDS itself only attempts file services via the shadow set virtual number.

  For example, to boot from a shadowed set known as DUS19, which contains members DUA2 and DUA9, and use DUA9 as the boot path in case booting via the shadow set virtual number fails, load R3 as follows:

```
>>> D/G 3 80130009
```

  o The device naming convention for a shadowed disk is HSC50$DUSnnn, where nnn is the shadow set virtual unit number between 0 and 255. This is in contrast to a non-shadowed HSC50 disk which has a device name format of HSC50$DUAnnn.

* BCA

  o The BCA, BI to CI Adapter, is now supported in a boot and load path.

  o The BCA is ATTACHed with device type CIBCA, as follows:

```
DS> ATTACH CIBCA HUB PAA0   ! BCA adapter
BI Node Number? 6
BR? 4
CI Node? 2
DS>
```

* Global Section Support for VSDP

  o The VDS now maps part of its control region into a global section, in order that VSDP can examine pass count, test number, subtest number, etc. The global section is only

established when the VDS is being run from a mailbox, and does not affect the operation of the supervisor or diagnostic programs.

2 BUG FIXES

- In command mode, the DELETE key was not being processed correctly by the supervisor in standalone mode on video terminals. The symptom would appear when a command was typed, and the user tried to erase the command by typing the delete key. Although the screen appeared correct, the VDS's internal command buffer was not being cleared, and the originally typed command would be executed. This has been fixed.

- When a SHOW MEMORY/BUFFER command was given just after a program had called $DS_RELBUF and no buffers had been allocated, the VDS displayed a negative number of pages allocated. This has been fixed.

- If memory management had previously been turned on via a $DS_MMON call, a SHOW MM command would not indicate that memory management was on. This has been fixed.

- In user mode, an access control violation occurred as a result of a DIRECTORY command to a disk whose device name did not conform to the ggan or name$ggan format. This has been fixed.

3 KNOWN BUGS AND DEFICIENCIES

1. If memory management is turned on with the SET MM ON command, and file access to an HSC50 disk is attempted, you may experience file read errors on 86xx machines. The message you may see is:

   %RMS-F-RER, file read error (R0=0001C0F4)

   or the file access may cause the VDS to hang.

RELEASE NOTES FOR
VAX-11 DIAGNOSTIC SUPERVISOR
VERSION 10.5, EZSAA only
January 26, 1987

1 ENHANCEMENTS

* Support for logical names and search lists in USER mode

  - VMS logical names and searchlist logical names are allowed to represent file specifications. If the equivalence string of the logical name includes only part of a directory specification, it will be concatenated with the supervisor's default directory. For example, if SYS$SYSROOT is equivalent to 1DUS0:[SYS3.], and you specify SYS$SYSROOT:[SYSMAINT], the resulting filespec will be 1DUS0:[SYS3.SYSMAINT].

  - This is supported for all VDS commands and services involving file operations.

* DIRECTORY command in USER mode

  - Previous versions of VDS required that you ATTACH a device before doing a DIRECTORY of that device. It is not necessary to ATTACH the device in Version 10.4 of VDS.

* USER mode default load path

  - The VDS now sets its initial default load path to the logical name SYS$MAINTENANCE. SYS$MAINTENANCE should be defined in the system logical name table to the disk and directory which contains the system's diagnostic programs. If it is not defined, see your system manager, or define it in your process's name table.

  - In order to change the default load path, use the SET LOAD command as before. You may use DCL to define an equivalence string for SYS$MAINTENANCE in your process logical name table in order to change the VDS's initial default load path.

  - The VDS sets the default disk and directory by redefining the SYS$DISK logical name with the $CRELOG system service, and changing the default directory with the $SETDDIR service. Thus, if you attempt to SET LOAD to SYS$DISK, the VDS will redefine the logical SYS$DISK to be equivalent to itself, and file services will fail.

* Volume Shadowing

  o The VDS now supports booting and loading diagnostics from a VMS shadow set.

  o In order to boot VDS from a shadow set, R3 should be set up for VMB in the following format:

    The virtual unit number corresponds to the unit number assigned to the shadow set. The member unit can be the physical drive number of any member of the shadow set. It is used by VMB and SYSBOOT during booting in case access via the shadow set virtual number fails. The VDS itself only attempts file services via the shadow set virtual number.

    For example, to boot from a shadowed set known as DUS19, which contains members DUA2 and DUA9, and use DUA9 as the boot path in case booting via the shadow set virtual number fails, load R3 as follows:

```
>>> D/G 3 80130009
```

  o The device naming convention for a shadowed disk is HSC50$DUSnnn, where nnn is the shadow set virtual unit number between 0 and 255. This is in contrast to a non-shadowed HSC50 disk which hes a device name format of HSC50$DUAnnn.

* BCA

  o The BCA, BI to CI Adapter, is now supported in a boot and load path.

  o The BCA is ATTACHed with device type CIBCA, as follows:

```
DS> ATTACH NBIA HUB NBIA0          ! NBI adapter
LOGICAL ADAPTER # 0
DS>
DS> ATTACH NBIB NBIA0 NBIB0        ! NBI adapter
BI # ? 0
BI Node Number (HEX) ? 2
DS>
DS> ATTACH CIBCA NBIB0 PAA0        ! BCA adapter
BI Node Number (HEX) ? 6
BR? 4
CI Node? 2
DS>
```

* Global Section Support for VSDP

  o The VDS now maps part of its control region into a global section, in order that VSDP can examine pass count, test number, subtest number, etc. The global section is only established when the VDS is being run from a mailbox, and does not affect the operation of the supervisor or diagnostic programs.

* Multiprocessor Enhancements

  o Breakpoints

    You can optionally set breakpoints in the code to be executed in attached processors. Whenever a breakpoint is reached by any processor, all processors are placed in their idle loops (except for the primary processor, which enters VDS command mode). Typing a CONTINUE command causes all processors to continue from the point they were stopped. Typing a NEXT command executes the next instruction only if the breakpoint was executed by the primary processor, so that you can only single step through code being executed in the primary processor.

    You can set one or more breakpoints on an Attached or Primary Processor but not both (no mixed bpt's).

    In addition, to be assured of hitting breakpoints in an Attached Processor, test code must be synchronized between the Primary and Attached CPU's such that if the Attached processor hits a breakpoint, the Primary processor would be able to report that breakpoint by issuing periodic calls (at least every three seconds) to the $DS_BREAK service.

    One simple method of accomplishing this is shown in the following test structure. Of course, other methods for synchronization using the $DS_BREAK service may exist.

```
Primary Processor code          Attached Processor Code
----------------------          -----------------------
    Set flag
    Start Attached Processor -----> BGNATTACHED
5$: BBC flag 10$                Execute test code
    $DS_BREAK                             .
    BRB 5$                                .
                                $DS_BREAK
                                Clear Flag
10$: Continue                         Here the Attached could
                                wait for another flag from
                                the Primary to continue.
```

    In this structure the attached can hit any breakpoint set between the BGNATTACHED and the clearing of the flag.

The Primary processor needs to loop on $DS_BREAK to be able to report an Ap breakpoint or condition and also to respond to control-C's. A sort of stop/go flag mechanism can be designed for the Primary and Attached to execute sections of test code where the Ap can perform a test, perhaps write results, and then signal the Primary, then the primary can continue and perhaps start another section of test code. It is important that $DS_BREAK 's be called from both the Primary and Attached Processors.

When an Attached Processor hits a breakpoint, the PC of the Primary Processor (that detected the breakpoint) will point to the instruction following the $DS_BREAK service that resulted in the Ap BPT message.

o Mp Diagnostic Users

If a diagnostic program not using the multiprocessor features of the VDS is executed under the new version of the VDS, the user will see no differences from current versions of the VDS. There will be two differences that a user will see when executing a program designed to run on multiple processors.

1. He/she will have to attach each processor he/she desires to be executed by the diagnostic program. However, this process is identical to the attaching sequences that are currently necessary for attaching any device before testing it.

2. In order to examine or deposit into the general purpose registers (GPRs) or internal processor registers (IPRs) of an attached processor, the user must specify the generic name of the processor (used in the ATTACH command) to indicate which processor's registers are to be examined or deposited into.

   It will not be possible to examine registers in an attached processor unless a diagnostic program has previously called the $DS_BOOTATTACHED service to boot that processor, and that attached processor has hit a breakpoint.

   A new command, SET CPU, will be added. This command will change the default processor referenced by the EXAMINE and DEPOSIT commands. For example, the command sequence

```
SET CPU KA1
EXAMINE R5
DEPOSIT R3 4
```

   will cause R5 to be examined and the value "4" to be deposited into R3 of the processor whose logical unit number is KA1.

To keep track of which registers are being examined or deposited to, another new command called SHOW CPU has been added. Typing a SHOW CPU will indicate either PRIMARY or the generic name of the Ap used in the Attach sequence.

- Mp Restrictions

  The following restrictions apply to users of diagnostic programs which make use of the multiprocessing facilities of the VDS:

  1. It will not be possible to use the VDS EXAMINE and DEPOSIT commands to examine or deposit into the IPRs of an attached processor unless that processor has previously been booted with the $DS_BOOTATTACHED service, and that processor has hit a breakpoint.

  2. The NEXT command (single-stepping) cannot be used for code executing in an attached processor. If it is desirable to single-step the Ap, then the user should deposit a halt at the point you wish to single-step the Ap, and set a breakpoint in the Primary Processor at a convenient place, such as after calling the $DS_STARTATTACHED service. When you start the test and hit the Ap halt instruction, you can then use console commands to single-step the Ap.

  3. The PC of an attached processor cannot be modified with the DEPOSIT command.

  4. Only the PSW portion of the PSL in an attached processor can be examined.

  5. Breakpoints can only be set for one processor at a time.

  6. The PC will not be indicated when continuing from a multiprocessor diagnostic since more that one processor may be resuming execution of code.

2 BUG FIXES

- In standalone mode, the time stamp in some VDS messages was appearing as "Jan. 1, 1986 0:0:0" even though the correct time and date would appear in other messages. This has been fixed.

- In command mode, the DELETE key was not being processed correctly by the supervisor in standalone mode on video terminals. The symptom would appear when a command was typed, and the user tried to erase the command by typing the delete key. Although the screen appeared correct, the VDS's internal command buffer was not being cleared, and the originally typed command would be executed. This has been fixed.

- When a SHOW MEMORY/BUFFER command was given just after a program had called $DS_RELBUF and no buffers had been allocated, the VDS displayed a negative number of pages allocated. This has been fixed.

- If memory management had previously been turned on via a $DS_MMON call, a SHOW MM command would not indicate that memory management was on. This has been fixed.

- In user mode, an access control violation occurred as a result of a DIRECTORY command to a disk whose device name did not conform to the ggan or name$ggan format. This has been fixed.

- When booting from an HSC disk connected to a CIBCI or CIBCA, the CI_NODE ptable contained the incorrect value in the functionality field (HP$L_CI_FUNC) and the CI node field (HP$B_CI_NODE). No symptom was reported other than a SHOW DEVICE command displaying the wrong information for the CI node. This has been fixed.

- If you control-C an mp diagnostic and then start and control-C a SHOW MEM command for example, the next CONTINUE command will result in a continuation of the mp diagnostic.

RELEASE NOTES FOR VAX-11 DIAGNOSTIC SUPERVISOR VERSION 10.6, EBSAA only Jan. 29, 1987

1 ENHANCEMENTS

- This version provides support for the 8250/8350 systems. These systems contain faster cpus than the original 8200/8300 systems. The VDS which supports the new systems is EBSAA.EXE. Note that the processor is still ATTACHed with device type KA820 for the 8250/8350 systems. The only services which are affected are the $DS_WAITMS and $DS_WAITUS, and these have been adjusted to account for the increased processor speed.

RELEASE NOTES FOR VAX-11 DIAGNOSTIC SUPERVISOR VERSION 10.7 March 23, 1987

1 ENHANCEMENTS

* This version provides support for the 8250/8350 systems. These systems contain faster cpus than the original 8200/8300 systems. The VDS which supports the new systems is EBSAA.EXE. Note that the processor is still ATTACHed with device type KA820 for the 8250/8350 systems. The only services which are affected are the $DS_WAITMS and $DS_WAITUS, and these have been adjusted to account for the increased processor speed.

* Ptables have been added for the LG01, LG02, and LG03 lineprinters.

2 BUG FIXES

* A bit field in the SBIA SILO register was being reported by the 86xx EDSAA.EXE as "Reserved" when it contained a value of 6. This occurred when the VDS interpreted SILO information after receiving SBIA Fault Interrupts. This has been corrected to report "Interrupt Summary Read".

* When a VDS command, which involved accessing a file, was executed while running under VMS, and the file was protected, VDS would report "Unknown error". This has been changed to report "Insufficient privilege or file protection violation".

* When using the VDS NEXT command to single step over an instruction which had a breakpoint set, the VDS display after the next command would show the 03 (BREAKPOINT) opcode instead of the original opcode. This has been fixed so that the "real" opcode is displayed.

RELEASE NOTES FOR VAX DIAGNOSTIC SUPERVISOR VERSION 10.8 June 22, 1987

1 ENHANCEMENTS

* Ptables and boot and load support have been added for the RA70 non-removable disk.

* Added ptables for DEBNA and DEBNK.

* Updated SHOW BREAKPOINT display and the breakpoint message (primary and attached processor) which is displayed when a breakpoint is reached, to include the base address and offset which were used when setting the breakpoint. For example,

```
DS> SET BASE 9010
DS> SET BREAKPOINT E
DS> SHOW BREAKPOINT
Breakpoints located at:
                0000901E(X)     (Base=00009010(X) Offset=0000000E(X))
```

when the breakpoint is reached the following will be displayed:

```
Breakpoint at: 0000901E(X)     (Base=00009010(X) Offset=0000000E(X))
DS>
```

2 BUG FIXES

* When a zero value was passed for one of the $DS_LOAD parameters (FILE, DEFAULT, ADDRESS, RETLEN, or RETREC), an access violation would occur when VDS tried to access the location with memory management turned on in the standalone mode, or when running under VMS. The supervisor was then changed so that the $DS_LOAD service checked these parameters for zero, and returned an error code if so. Unfortunately, this change caused several diagnostics to fail by not allowing them to load files (usually microcode) into memory. So far, EVMAE and EVDFD are known to experience this problem. This problem exists in VDS versions 10.0 (EBSAA prerelease), 10.1 (EZSAA prerelease), 10.2 (release 25 and 26), 10.4 (rel. 27), 10.5 (EZSAA prerelease), 10.6 (EBSAA 8250 prerelease) and 10.7 (rel. 28).

Some of these diagnostic programs were not affected by the access violation because they do not run under VMS or in standalone with memory management turned on. So that these diagnostic programs do not have to be rereleased, the VDS will no longer return an error code when a parameter of zero is passed. For those programs which are required to run with memory management enabled, the access violations should be caught by developers when executing the QA checklist in the section which requires memory management to be enabled. Those diagnostics should be fixed.

* If a breakpoint in a diagnostic program was reached after a $DS_SETVEC macro had been performed to capture the machine check (04), translation not valid (24), access violation (20), or reserved operand (18) vectors, any EXAMINE or DEPOSIT command which resulted in one of these faults would cause control to pass to the diagnostic program's exception handler.

  This has been fixed by changing the EXAMINE and DEPOSIT commands to reset these vectors in the system control block for the duration of the EXAMINE or DEPOSIT command. A side effect of this change is that if the VDS EXAMINE command is used to EXAMINE these SCB vectors in this scenario, the normal VDS SCB vectors will be returned. To examine the vectors as set by the diagnostic program, use the console EXAMINE command.

* The parameter generic-name for DEATTACH command MUST be specified now. DEATTACH command also takes 'ALL' as a keyword parameter to de-attach all devices attached to the link, excluding the link itself. VDS User's Guide will be updated correspondingly.

* Previously, if the VDS was booted from a disk connected to an HSC50, you could not load diagnostics from a different disk/HSC50 (one other than an HSC50 specified as the failover path in R2 at boot time) by ATTACHing and setting the default load path to it. The VDS would still try to access the disk via the primary or failover HSC50 path which was specified in R2. This has been fixed.

* A hanging problem which was amplified by Rev 22E console program appeared in EZSAA while running in a script file involving a lots of terminal I/O. EZSAA console modules CONSOLE8800 and CSDUBTDRV are modified to catch a missing XON sent from console to resume from holding data.

* Fixed the bug in supporting DHB32.

* Fixed the bug in booting VDS from KDB50 and UDA50.

RELEASE NOTES FOR
VAX DIAGNOSTIC SUPERVISOR

VERSION 10.9
Sep. 21, 1987

1 NEW DEVICE SUPPORT

* Added ptable descriptor for RV20.

* Bliss support for DHB32. Added Bliss definitions for DHB32 in Bliss DIAG library so that any diagnostic written in Bliss can use those definitions.

2 ENHANCEMENTS

* In the past, a boot device, either DWBUA, KDB50, CIBCI, or KFBTA, had to be selftested again after the initialization done by its device driver in VMB. This redundancy has been eliminated in a BI system.

* Boot and load support for 2nd console RX50 drive on 82xx/83xx systems. Previously, VDS could be booted from one console RX50 drive called CSA0 only. Now, an operator can have the options of booting VDS from either CSA1 or CSA2.

3 BUG FIXES

* When a device is specified without a colon for the 'SET LOAD' command, a colon will be automatically postfixed to the device name. Prior to the fix, a VDS command 'SET LOAD DBA2', for example, appeared to succeed, but did not change the default to device DBA2 because it did not actually recognize DBA2 as a device without a postfixed colon.

* A directory specification for 'SET LOAD' command was not parsed the same way as by VMS. For example, VDS did not take 'SET LOAD RELD$1:[28]' as a legal command while 'SET DEFAULT RELD$1:[28]' is perfectly fine with VMS. This was because VDS treated a number in a directory specification as an octal format of UIC, which invalidated a number with digits higher than seven. VDS is now made consistent with VMS by generalizing any number as alphanumeric format of either a UIC or a name of a directory.

* VDS used to reject a device with unit number 255. For example, a VDS attach command 'ATTACH RABO HUB DUA255' would cause an error message of 'Unit number too big or not allowed'. This was due to an error in treating a maximum unit number. It has been fixed.

RELEASE NOTES FOR
VAX DIAGNOSTIC SUPERVISOR
VERSION 10.10
Dec. 21, 1987

1 NEW SYSTEM SUPPORT

2 NEW DEVICE SUPPORT

* Added ptables for DEBNA, DEBNT and LANCE.

3 ENHANCEMENTS

* Supervisor onboard image PCS750.BIN has been upgraded to Rev. 99.

4 BUG FIXES

* $DS_ASKSTR macro could not be used by BLISS source because R1 containing returned pointer could not be easily referenced by caller. The register can now be referenced by BLISS source with Linkage-Declarations.

* Encountered a 'Reserved/privileged instruction fault' while attempting to do a 'SHOW MEM/DAT' after running EVKAE. It has been soloved by checking for proper mode before accessing privileged register.

* The bug occasionally causing access violation during 'DIRECTORY' command in online mode has been fixed. This problem has existed since VDS Ver. 10.3. Its PC at error is somewhere near address 00026000.

RELEASE NOTES FOR

VAX DIAGNOSTIC SUPERVISOR
VERSION 10.11
Mar. 21, 1988

1 NEW SYSTEM SUPPORT

* Announcement for the support of LYNX system.

  The VAXstation 8000 (LYNX) is the newest member of the VAXstation family. It is a high performance, 3D, full color workstation developed jointly by Digital and Evans & Sutherland Corp. It offers the fastest vector drawing speed in the industry, over 500,000 3D vectors per second.

  All VAXstation 8000 systems include the following hardware:

  - Custom Under Desk Pedestal
  - VAX 8250 CPU
  - 16 Mbyte Memory
  - TK50 Tape Drive and Control
  - Ethernet Control
  - RD54 disk and Control
  - Graphics Subsystem, 58 planes
  - VR290 Color Monitor
  - Peripheral Repeater Box-graphic input devices multiplexer
  - 8 Knob Dial Box with programmable LEDs
  - VSXXX-AA Mouse

VDS MEDIA AND BOOT SPECIFICATION

a) VDS (EBSAA Rev. 10.11) can now be booted from a TK50 cassette tape driver on LYNX. The controller for TK50 is DEBNK. Load support for a TK50 is also added so that we can load a file or get a directory of file(s) from a TK50 under control of EBSAA.

   To create a bootable TK50 cassette tape, first copy VMB.EXE that supports TK50 booting to the tape. This must be the first file on the tape for the system boot roms to read it in. For fast booting copy DIAGBOOT.EXE next followed by EBSAA.EXE. These are the minimal files required for booting from the tape.

   For optimum speed of access, the files should be copied to the tape in the order they will be read.

   Because of a format restriction in VMB.EXE and DIAGBOOT.EXE, these files and EBSAA.EXE must be copied in the block size of 512 bytes and the remaining files can be copied in a bigger block size to gain faster operation of the TK50.

   The steps for making a bootable tape follow:

```
        1) Initialize the tape.
        2) MOUNT/BLOCK_SIZE=512
           COPY VMB.EXE,DIAGBOOT.EXE,EBSAA.EXE MUL6:
        3) The tape will have to be dismounted now
           DISMOUNT/NOUNLOAD
        4) Mount the tape with a bigger block size (e.g.)
           MOUNT/BLOCK_SIZE=16384
        5) Now copy rest of your files to the tape.

        If your tape does not have to be bootable, then skip steps 2
        and 3.

    b) VDS (EBSAA Rev. 10.11) can now be booted from a RD52, RD53 or
       RD54 Winchester hard disk on LYNX. The controller for the
       Winchester hard disk is KFBTA. Load support for the Winchester
       hard disk is also added so that we can load a file or get a
       directory of file(s) from the Winchester hard disk under control
       of EBSAA.

       To create a bootable Winchester hard disk, we should copy
       VMB.EXE, DIAGBOOT.EXE and EBSAA.EXE to the disk in File-11
       format.

       The steps for making a bootable disk follow:

       1) $ ALLOC DUan:
       2) $ INIT DUan:
       3) $ MOUNT/OVER=ID DUan:
       4) $ CREATE/DIR DUan:[SYSMAINT]
       5) $ COPY VMB.EXE, DIAGBOOT.EXE, EBSAA.EXE DUan:[SYSMAINT]
       6) $ COPY DIAGNOSTIC.NAME DUan:[SYSMAINT]
       7) $ MCR WRITEBOOT
            Target system device (and boot file if not VMB.EXE): <retn>
            Enter VBN of boot file code (default is 1): <retn>
            Enter load address of primary bootstrap in HEX
            (default is 200): <retn>

Added ptables for DEBNA, DEBNK, KFBTA, LANCE, TK50, RD52, RD53, and
RD54.

   For DEBNA: Description:   DEBNA BI Network Adapter
              Link:          HUB
              Generic name:  ETa
              Additional information: BI Node Number (HEX)? [hex 0-F]

   For DEBNK: Description:   DEBNK Cartridge Tape Controller
              Link:          HUB
              Generic name:  ETa
              Additional information: BI Node Number (HEX)? [hex 0-F]

   For KFBTA: Description:   KFBTA BI Disk Adapter
              Link:          HUB
              Generic name:  DUa
              Additional information: BI Node Number (HEX)? [hex 0-F]
```

For LANCE: Description: Local Area Network Comm Ethernet
Link: ETa
Generic name: ETan

For TK50: Description: TK50 Tape Drive and Cartridge
Link: ETa
Generic name: MUan

For RD52: Description: RD52 Winchester hard disk
Link: DUa
Generic name: DUaxx

For RD53: Description: RD53 Winchester hard disk
Link: DUa
Generic name: DUaxx

For RD54 Description: RD54 Winchester hard disk
Link: DUa
Generic name: DUaxx

* Announcement for the de-support of VAX 11/730 and VAX 11/725 systems.
a) The VDS which support VAX 11/730 and VAX 11/725 (ENSAA) will no longer be distributed in general releases.
b) Bug fixes to ENSAA, version 10.10, which was archived in release 31, will be done as needed.

2 NEW DEVICE SUPPORT

* Boot and load supports have been added for disk driver RA90.

3 ENHANCEMENTS

* Enhanced VDS ptable descriptors, ptables, and VDS internals to support high unit number which has to be in a word allocation.

4 BUG FIXES

* The old data structure in macro $DS_PRINTREV was statically set up for up to 4 logical units. However, there is no such limitation documented in the VAX Diagnostic Design Guide. We have modified the macro to dynamically allocate one data

block for each logical unit and allow each device unit to have up to four modules (boards). Therefore, the limitation to the number of logical units in $DS_PRINTREV will be consistent with the number of ptables (128) we can have at one time. In addition, the macro has been enhanced to give warning message to an user and return error status in register R0 in case of improper use.

* On a Nautilus system, examining non-existent I/O addresses would get 0's returned and set the NEX bit in bus error register instead of the message "No response/invalid operation at: xxxxxxxx". This is because a Nautilus system will not generate a hardware machine check for accessing non-existent I/O address, which in turn results an error message. New codes have been added to detect the NEX bit set and simulate the result of a machine check.

* When using START/TIME=xx:xx:xx.xx, if the user types a C and continues, the diagnostic used to run infinitely. This is now fixed for all VDS's.

Image Synopsis

```
Virtual memory allocated:                 00010000 00036FFF 00027000 (159744. bytes, 312. pages)
Stack size:                                     20. pages
Image header virtual block limits:               1.       1. (    1. block)
Image binary virtual block limits:               2.     313. (  312. blocks)
Image name and identification:            ECSAA 10.11
Number of files:                                97.
Number of modules:                              99.
Number of program sections:                     20.
Number of global symbols:                     1262.
Number of cross references:                   2896.
Number of image sections:                        6.
User transfer address:                    00031435
Image type:                               EXECUTABLE.
Map format:                               FULL WITH CROSS REFERENCE in file DISK$DS:[DS.LOCAL.RELEASE.WORK]ECSAA.MAP;1017
Estimated map length:                     371. blocks
```

Link Run Statistics

Performance Indicators	Page Faults	CPU Time	Elapsed Time
Command processing:	565	00:00:14.16	00:00:40.59
Pass 1:	473	00:00:15.85	00:00:51.25
Allocation/Relocation:	103	00:00:00.83	00:00:03.02
Pass 2:	316	00:00:17.19	00:00:53.03
Map data after object module synopsis:	19	00:00:09.11	00:00:31.14
Symbol table output:	0	00:00:00.03	00:00:00.31
Total run values:	1476	00:00:57.17	00:02:59.34

```
Using a working set limited to 3012 pages and 1090 pages of data storage (excluding image)

Total number object records read (both passes):   12906
    of which 157 were in libraries and 3985 were DEBUG data records containing 1517659 bytes

Number of modules extracted explicitly              = 0
    with 6 extracted to resolve undefined symbols

219 library searches were for symbols not in the library searched

A total of 0 global symbol table records was written

Symbol table output	2	00:00:00.04	00:00:00.23
Psect synopsis output	2	00:00:00.00	00:00:00.00
Cross-reference output	3	00:00:00.03	00:00:00.06
Assembler run totals	1805	00:00:04.77	00:00:07.80

The working set limit was 2400 pages.
198028 bytes (387 pages) of virtual memory were used to buffer the intermediate code.
There were 60 pages of symbol table space allocated to hold 1161 non-local and 15 local symbols.
338 source lines were read in Pass 1, producing 73 object records in Pass 2.
24 pages of virtual memory were used to define 23 macros.

Macro library statistics

Macro library name	Macros defined
DISK$DS:[DS.LOCAL.RELEASE.WORK]DS.MLB;1	0
DISK$DS:[DS.LOCAL.RELEASE.WORK]DIAG.MLB;1	9
DISK$DS:[DS.LOCAL.RELEASE.WORK]PAMAC.MLB;1	0
SYS$COMMON:[SYSLIB]LIB.MLB;2	2
SYS$COMMON:[SYSLIB]STARLET.MLB;2	8
SYS$COMMON:[SYSLIB]STARLET.MLB;2	0
TOTALS (all libraries)	19

1544 GETS were required to define 19 macros.

There were no errors, warnings or information messages.

;    0032  0      ! ABSTRACT:
;    0033  0      !
;    0034  0      !       These modules simulate the function of the respective
;    0035  0      !       RMS functions.
;    0036  0      !
;    0037  0      ! AUTHOR:       Roger Riggs, CREATION DATE: 10-November-1979
;    0038  0      !
;    0039  0      ! MODIFIED BY:
;    0040  0      !
;    0041  0      !               Dave Butenhof, 07-oct-1980, version 6.1
;    0042  0      !       01      To allow support of magtape directory command which will
;    0043  0      !               function in standalone or user mode, support minimal level
;    0044  0      !               of wildcarding.  "*" means open next file on tape, return
;    0045  0      !               full file name in NAM block if any.  There is no wildcard
;    0046  0      !               context of any sort; the caller must remember the first
;    0047  0      !               file it found, and exit the wildcard loop when that name
;    0048  0      !               is repeated.  This is for Supervisor use only and will not
;    0049  0      !               be documented outside the program listings of ANSI and
;    0050  0      !               DIRECTORY.
;    0051  0      !                                                                        !G:2
;    0052  0      !       02      Support version numbers
;    0053  0      !               Roger Riggs, 22-oct-1980
;    0054  0      !                                                                        !G:2
;    0055  0      !       03      Added code to implement FAB$V_RWO rewind on open.
;    0056  0      !               The magtape is rewound before the search for the file begins.
;    0057  0      !               also added to code to issue IO$_drvclr before first operation.

```
The working set limit was 2400 pages.
23823 bytes (47 pages) of virtual memory were used to buffer the intermediate code.
There were 10 pages of symbol table space allocated to hold 66 non-local and 0 local symbols.
111 source lines were read in Pass 1, producing 22 object records in Pass 2.
9 pages of virtual memory were used to define 8 macros.
```

                    54 ;               Roger Riggs, 28-May-1980, Version 5.4
                    55 ;       04      Added code to check that on APT PTEXT command
                    56 ;               that there is at least one command to process.
                    57 ;
```

```
0000     58 ;        05      - Jack Stansbury, 22-Oct-1981, Version 6.-
0000     59 ;                Changed SEP Psect to CODE.
0000     60 ;                Fixed truncation errors. Change to lower case on message.
0000     61 ;                Also added .LIBRARY statements for $DS and $DIAG.
0000     62 ;
0000     63 ;        06      - Jack Stansbury, 12-Oct-1981, Version 6.-
0000     64 ;                Changed the call to DS$PARSE to DSX$SUPERPARSE. See the CLI
0000     65 ;                module for an explanation of SUPERPARSE. It returns with the
0000     66 ;                low bit clear in R0 if anything went wrong.
0000     67 ;
0000     68 ;        07      - Jack Stansbury, 12-Oct-1981, Version 6.-
0000     69 ;                Took out references to HALTD and HALTI. Made them just HALT.
0000     70 ;
0000     71 ;        08      - Jack Stansbury, 3-Feb-1982, Version 6.6
0000     72 ;                Added a .LIBRARY statement for LIB. Note: This .LIBRARY
0000     73 ;                statement must be the first one since the libraries are
0000     74 ;                searched in LIFC (Last-In, First-Checked) order.
0000     75 ;
0000     76 ;        09      Bob Bergazzi    2-Feb-1983      Version 6.11
0000     77 ;                Added code to COM_PTEXT that clears out DS$GL_CLIBASE.
0000     78 ;                We should clear these flags out on every command,
0000     79 ;                otherwise subsequent commands may be affected by previous
0000     80 ;                commands. This coincides with a change to APT which allows
0000     81 ;                any commands as PTEXT. The bug prompting this was
0000     82 ;                SET EVENT 1, CLEAR EVENT 1, which caused a hung load.
0000     83 ;
0000     84 ;        10      Bob Bergazzi    11-Apr-1983     Version 6.11
0000     85 ;                Fixed the previous edit.
0000     86 ;                                                                        ;G:6
0000     87 ;        11      STEVE MEIER     23-jun-1986     Version 10.2            ;G:6
0000     88 ;                changed literal to symbolic string ( "DS> " ).          ;G:6

Performance indicators

Phase	Page faults	CPU Time	Elapsed Time
Initialization	25	00:00:00.00	00:00:00.19
Command processing	930	00:00:00.30	00:00:00.98
Pass 1	565	00:00:01.22	00:00:02.74
Symbol table sort	0	00:00:00.07	00:00:00.07
Pass 2	24	00:00:00.29	00:00:00.46
Symbol table output	2	00:00:00.02	00:00:00.16
Psect synopsis output	2	00:00:00.00	00:00:00.01
Cross-reference output	5	00:00:00.14	00:00:00.19
Assembler run totals	1555	00:00:02.04	00:00:04.80

The working set limit was 2400 pages.
73184 bytes (143 pages) of virtual memory were used to buffer the intermediate code.
There were 20 pages of symbol table space allocated to hold 291 non-local and 15 local symbols.
311 source lines were read in Pass 1, producing 30 object records in Pass 2.
24 pages of virtual memory were used to define 18 macros.

Macro library statistics

Macro library name	Macros defined

Symbol table output	2	00:00:00.03	00:00:00.06
Psect synopsis output	2	00:00:00.00	00:00:00.00
Cross-reference output	4	00:00:00.04	00:00:00.05
Assembler run totals	1738	00:00:04.16	00:00:08.13

The working set limit was 2400 pages.
155496 bytes (304 pages) of virtual memory were used to buffer the intermediate code.
There were 70 pages of symbol table space allocated to hold 1254 non-local and 15 local symbols.
338 source lines were read in Pass 1, producing 82 object records in Pass 2.
21 pages of virtual memory were used to define 20 macros.

Macro library statistics

Macro library name	Macros defined
DISK$DS:[DS.LOCAL.RELEASE.WORK]DS.MLB;1	0
DISK$DS:[DS.LOCAL.RELEASE.WORK]DIAG.MLB;1	3

The working set limit was 2400 pages.
82723 bytes (162 pages) of virtual memory were used to buffer the intermediate code.
There were 40 pages of symbol table space allocated to hold 674 non-local and 1 local symbols.
141 source lines were read in Pass 1, producing 53 object records in Pass 2.
15 pages of virtual memory were used to define 14 macros.

Cross-reference output	4	00:00:00.03	00:00:00.07
Assembler run totals	1653	00:00:03.46	00:00:06.38

```
The working set limit was 2400 pages.
114580 bytes (224 pages) of virtual memory were used to buffer the intermediate code.
There were 50 pages of symbol table space allocated to hold 813 non-local and 20 local symbols.
460 source lines were read in Pass 1, producing 58 object records in Pass 2.
26 pages of virtual memory were used to define 25 macros.
```

Macro library statistics

Macro library name	Macros defined

0000    53 ;               Added $DS_$ADD and $DS_$COMPLEMENT operations to
0000    54 ;               PT-descriptor interpreter
0000    55 ;                                                                       ;G:3
0000    56 ;       [04]    Dave Butenhof, 24-sep-1980, Version 6.1                 ;G:3
0000    57 ;               Split DSV$ATTACH routine into DSV$ATTACH control routine
```

```
0000     58 ;                  and DSX$ATTACH, which is callable by diagnostics and will
0000     59 ;                  cause no typeout or console/script reads.  The primary
0000     60 ;                  purpose is to support the AUTOSIZER.
0000     61 ;                                                                          ;G:3
0000     62 ;          [05]    Dave Butenhof, 19-dec-1980, Version 6.2                 ;G:3
0000     63 ;                  Implement MCT as NEBULA 'central bus'.  Also generalize
0000     64 ;                  'central bus' string compares, and generate error if
0000     65 ;                  the wrong 'central bus' name is typed (e.g., 'CMI' for 780).
0000     66 ;                                                                          ;G:3
0000     67 ;          [06]    Dave Butenhof, 30-mar-1981, version 6.3                 ;G:3
0000     68 ;                  Implement new 'hub' structures, cross-implementation-wise:
0000     69 ;                  'HUB' and 'PHAD'.
0000     70 ;                                                                          ;G:3
0000     71 ;          [07]    Marion Baggett, 2-Oct-1981 Version 6.-                  ;G:3
0000     72 ;                  Print only device and type fields for /BRIEF switch
0000     73 ;                  on SHOW DEVICE, and SHOW SELECT commands.
0000     74 ;                                                                          ;G:3
0000     75 ;          [08]    Dave Butenhof, 20-Oct-1981, version 6.-                 ;G:3
0000     76 ;                  Fix a bug in Ptable descriptor location routine.
0000     77 ;                                                                          ;G:3
0000     78 ;          [09]    Dave Butenhof, 22-Oct-1981, version 6.-                 ;G:3
0000     79 ;                  Add ATTACH control C handler.  Also new Ptable
0000     80 ;                  descriptor commands $DS_$LOGICAL and $DS_$CASE.
0000     81 ;                                                                          ;G:3
0000     82 ;          [10]    Jack Stansbury, 27-Oct-1981, Version 6.-                ;G:3
0000     83 ;                  Fixed truncation errors.
0000     84 ;                                                                          ;G:3
0000     85 ;          [11]    Dave Butenhof, 06-Nov-1981, Version 6.-                 ;G:3
0000     86 ;                  Implemented SELECT/ADAPTER and DESELECT/ADAPTER.
0000     87 ;                                                                          ;G:3
0000     88 ;          [12]    Dave Butenhof, 18-Nov-1981, version 6.5                 ;G:3
0000     89 ;                  Implement DEATTACH command.
0000     90 ;                                                                          ;G:3
0000     91 ;          [13]    Dave Butenhof, 20-Nov-1981, version 6.5                 ;G:3
0000     92 ;                  Convert all PRINT's to use type codes, and delete unused
0000     93 ;                  message 't_insfmem'.
0000     94 ;                                                                          ;G:3
0000     95 ;          [14]    Dave Butenhof, 24-Feb-1982, version 6.6                 ;G:3
0000     96 ;                  Convert parsing of Device type field to allow use of
0000     97 ;                  '_' in the name (e.g., 'CI_NODE').
0000     98 ;                                                                          ;G:3
0000     99 ;          [15]    Dave Butenhof, 02-Mar-1982, version 6.6                 ;G:3
0000    100 ;                  Correct bug in SELECT/DESELECT: If /Adapter not specified,
0000    101 ;                  and device is duplicated, only first found is acted on, and
0000    102 ;                  no message is given.  Due to SELECT sorting, it may not even
0000    103 ;                  be possible to DESELECT that device (without /Adapter).
0000    104 ;                  Solution: Give error if no /Adapter on duplicate name.
0000    105 ;                                                                          ;G:3
0000    106 ;          [16]    Dave Butenhof, 10-Mar-1982, version 6.6                 ;G:3
0000    107 ;                  Correct some truncation errors.
0000    108 ;                                                                          ;G:3
0000    109 ;          [17]    Dave Butenhof, 07-Apr-1982, version 6.7                 ;G:3
0000    110 ;                  Add support for new Ptable descriptor directive, $DS_$NAME;
0000    111 ;                  this will allow use of enforced generic naming conventions,
0000    112 ;                  and inherited device names, while remaining compatible with
0000    113 ;                  the current schema.  Note that this directive must IMMEDIATELY
0000    114 ;                  follow the $DS_$INITIALIZE directive, and is treated as an
```

```
0000    115 ;               extension of same.
0000    116 ;                                                                   ;G:3
0000    117 ;       [18]    Jack Stansbury, 13-Apr-1982, Version 6.7            ;G:3
0000    118 ;               Fixed two truncation errors.
0000    119 ;                                                                   ;G:3
0000    120 ;       [19]    Dave Butenhof, 06-May-1982, Version 6.8             ;G:3
0000    121 ;               Make modifications (very minor) to support splitting
0000    122 ;               PTD$M_INHERITED into two separated bits, PTD$M_INHERIT_PRE
0000    123 ;               to inherit device prefix, and PTD$M_INHERIT_CON to inherit
0000    124 ;               controller designation.
0000    125 ;
0000    126 ;       [20]    Marion Baggett, 6-Oct-1982 Version 6.9              ;G:3
0000    127 ;               When inserting PTABLE for RB730, do not re-adjust the RB730
0000    128 ;               PTABLE for CSR values.  The RB730 is not on the the unibus.
0000    129 ;
0000    130 ;       [21]    Domenic Andella, 13-Apr-82 Version 6.11             .;G:3
0000    131 ;               Added central bus name "ABUS" to CENTRAL_BUS list, and
0000    132 ;               changed constant in DSX$ATTACH routine, GET_LINK label
0000    133 ;               from 3 to 4 to account for new central bus name.
0000    134 ;
0000    135 ;       [22]    John Ciukaj     14-Apr-1983     Version 6.11
0000    136 ;               - Inhibit device allocation in user mode during
0000    137 ;                 Select operation if 'Inhibit Allocate' bit is
0000    138 ;                 set in CRD Flags
0000    139 ;
0000    140 ;       [23]    Domenic Andella 14-Apr-83       Version 6.11
0000    141 ;               Corrected bug in DSX$ATTACH routine, GET_LINK label
0000    142 ;               to check all CPU link names.
0000    143 ;
0000    144 ;       [24]    M. Baggett      11-MAY-1983     VERSION 6.11
0000    145 ;               Changed ptd$m_name to mean alphanumeric.
0000    146 ;
0000    147 ;       [25]    Bob Bergazzi    May 16,1983     Version 6.11
0000    148 ;               Changed the order of the .LIB statements.
0000    149 ;
0000    150 ;       [26]    M. Baggett      10-OCT-1983     VERSION 6.13
0000    151 ;               Change to support HSC50 disk/tape names of the form
0000    152 ;               name$GGannn, where 'name' is a maximum
0000    153 ;               of 6 characters and 'GG' is the generic name and is
0000    154 ;               present with a controller letter and unit number.
0000    155 ;
0000    156 ;       [27]    Domenic Andella 16-FEB-1984     VERSION 6.13
0000    157 ;               Add code in GET_LINK to add offset of X200 to
0000    158 ;               ptable vector field if attached to SBIA 1 for
0000    159 ;               an 8600 CPU.
0000    160 ;
0000    161 ;       [28]    RE MUSE         11 MAY 1984     Version 7.0
0000    162 ;               added code to handle long device names (15 characters)
0000    163 ;               of the form 'node$device'.
0000    164 ;
0000    165 ;       [29]    Ted Salem       09 AUG 1984     Version 7.1         ;G:3
0000    166 ;               Added code to check if /noallocate is present in
0000    167 ;               the select command.
0000    168 ;
0000    169 ;       [30]    Ted Salem       29 AUG 1984     Version 7.1
0000    170 ;               Modified SHOW SELECT and SHOW DEVICE commands so that the returned |
0000    171 ;               will contain information on the devices' allocation status.
```

```
0000   172 ;
0000   173 ;       [31]    Amy Iorio       16 OCT 1984     Version 7.1
0000   174 ;               Added allocation class to possible device names
0000   175 ;               user may declare.
0000   176 ;
0000   177 ;       [32]    M. Baggett      14-Nov-1984     Version 7.1
0000   178 ;               Fixed bugs in [31] and clean up some coding.
0000   179 ;
0000   180 ;       [33]    Richard E. Muse 18-Jan-1985     VERSION 6.13
0000   181 ;               If adapter being attached is on a BI. Need to
0000   182 ;               add code to GET_LINK such that the  HP$W_VECTOR
0000   183 ;               field contains the correct BI offset.
0000   184 ;
0000   185 ;       [34]    Ted Salem       22-Jan-1985     Version 8.1
0000   186 ;               Fixed a /noallocate problem.
0000   187 ;
0000   188 ;       [35]    R.E. Muse       9-MAY-1985      Version 8.2                     ;G:3
0000   189 ;               removed cpu specific code that check for the vector
0000   190 ;               offset requirement - this code was placed in their
0000   191 ;               respective "ONLYnnn" modules for each different cpu type.
0000   192 ;
0000   193 ;               Jason Mi        12-May-1987     Version 10.8                    ;G:6
0000   194 ;               Added ALL as a keyword paramater to DEATTACH command.           ;G:6
0000   195 ;
0000   196 ;               David Gearin    07-Jul-1987     Version 10.9                    ;G:8
0000   197 ;               If max unit # is equal to 255 do not decrement the              ;G:9
0000   198 ;               the maximum unit # by one. [temp fix]                           ;G:9
0000   199 ;                                                                               ;G:8

```
                        .SBTTL  DSX$ATTACH      Process ATTACH command

;++
; Functional description:
;       This routine is called from DSV$ATTACH to translate an attach
;       command line using a PTABLE descriptor, and create a PTABLE
;       from this data.  If any argument is missing or invalid, it will
;       return with the given prompt string buffer set to the correct
;       prompt to get more data from the operator, and the input line
;       descriptor re-set to exclude the remaining (if any) incorrect
;       text of the input line.
;
; Calling sequence:
;       DS$ATTACH (cmdline, [prompt])
;
; Input Parameters:
;       cmdline         pointer to command line descriptor
;       prompt          pointer to ASCIC-type buffer (with length of remainder
;                       of buffer in byte 1)
;
; Implicit inputs:
;       none
;
; Output Parameters
;       prompt          the buffer is filled with an ASCIC string suitable for
;                       prompting the operator for the next ATTACH parameter.
; Implicit outputs:
;       none
;
; Side Effects:
;       If successfull, creates a PTABLE in dynamic pool space
;
; Register usage:
;       R4,R5           Descriptor of remaining input string
;       R6              Pointer to prompt string descriptor
;       R8              Pointer to input descriptor
;       R10             PTABLE descriptor "PC" for decode
;       R11             Pointer to PTABLE
;
; Return codes:
;       DS$_BADTYPE     Device type argument is bad (no PTABLE descriptor)
;       DS$_BADLINK     Device given as link is not attached
;       DS$_ILLUNIT     Unit number not given or was illegal (too big)
;       DS$_DEVNAME     Invalid device name given
;       SS$_BADPARAM    Number was in bad radix or out of range
;       SS$_INSFARG     Too few arguments given to complete ATTACH
;--

0716  1168
0716  1169 ;++
0716  1170 ; FUNCTIONAL DESCRIPTION:
0716  1171 ;
0716  1172 ;       This routine is used to interpret the P-table descriptor
0716  1173 ;       which builds the P-table for the current unit.
0716  1174 ;       Each OP code is examined and executed.  If during the
0716  1175 ;       execution input text is required, the input string is examined
0716  1176 ;       if the string is empty the input routine is called to get input.
0716  1177 ;
0716  1178 ; CALLING SEQUENCE:
0716  1179 ;
0716  1180 ;       PT$INTERPRET (INITPC, BASE, TEXT, PROMPT)
0716  1181 ;

Assembler run totals	2233	00:00:07.47	00:00:12.71

```
The working set limit was 2900 pages.
240429 bytes (470 pages) of virtual memory were used to buffer the intermediate code.
There were 70 pages of symbol table space allocated to hold 1064 non-local and 207 local symbols.
2774 source lines were read in Pass 1, producing 102 object records in Pass 2.
51 pages of virtual memory were used to define 39 macros.
```

                                0000     63 ;               Change error code from DS$_NOSUPPORT to DS$_UNSUPPDEV ;G:2
                                0000     64 ;                                                                    ;G:2
                                0000     65 ;       25      M. Baggett      16-Jan-1986     VDS 9.1
                                0000     66 ;               Removed HALT and added error status for unsupported
                                0000     67 ;               load devices.
                                0000     68 ;
                                0000     69 ;       24      M. Baggett      20-Sep-1985     VDS 9.0
                                0000     70 ;               Added back changes for AURORA.
                                0000     71 ;
                                0000     72 ;       23      Jim Shelhamer   12-Sept-1985    Version 8.3
                                0000     73 ;               Reset BOO$GL_UMR_TMPL. It gets set up for UNIBUS
                                0000     74 ;               devices, but fails to be reset for MASSBUS devices.
                                0000     75 ;               Also, went to better revision numbering, ie [23] not
                                0000     76 ;               [0223], which runs off the listing.
                                0000     77 ;
                                0000     78 ;       0222    Bob Bergazzi    July 25,1985    Version  8.3
                                0000     79 ;               Add code from BDABTDRIVR to set up pseudo map register
                                0000     80 ;               address in EXE$GL_UMR_PHY and EXE$GL_UMR_VIR.
                                0000     81 ;
                                0000     82 ;       0221    Bob Bergazzi    July 24,1985    Version 8.3
                                0000     83 ;               Made compatible with VMB version 13.
                                0000     84 ;
                                0000     85 ;       0220    Bob Bergazzi    June 3, 1985    Version 8.3
                                0000     86 ;               Added fixed data areas onto BOO$AL_VECTOR in order to be
                                0000     87 ;               compatible with VMS bootdrivrs.
                                0000     88 ;
                                0000     89 ;       0219    Bob Bergazzi    Jan. 16, 1985   Version 8.1
                                0000     90 ;               Added real BOO$PURDPR for 11/8SS.
                                0000     91 ;
                                0000     92 ;       0218    Bob Bergazzi    Nov. 20,1984
                                0000     93 ;               Added code for the 11/8SS cpu to BOO$PURDPR. Also, moved
                                0000     94 ;               edit which makes BOO$SELECT global into the .ENH from the
                                0000     95 ;               .UPD due to an edit clash.
                                0000     96 ;
                                0000     97 ;       0217    Bob Bergazzi    27-May-1983
                                0000     98 ;               Added another dispatch for CPU XXX in the CPUDISP MACRO.
                                0000     99 ;               This edit was put in by the supervisor group in the .ENH
                                0000    100 ;               file because the edit applies to a change in the .ENH file.
                                0000    101 ;               Eventually a new BOOTDRIVR module may be taken from VMS
                                0000    102 ;               which has the correct code in it.
                                0000    103 ;
                                0000    104 ;       DS02    Marion Baggett, 4-March-1983 Version 6.11
                                0000    105 ;               Added support for HSCCI booting.
                                0000    106 ;
                                0000    107 ;       DS01    Roger Riggs, 24-oct-1980, version 6.1
                                0000    108 ;               Added changes to version 4 VMB/BOOTDRIVR to make it usable
                                0000    109 ;               as bootdrivers for the Diagnostic Supervisor.
                                0000    110 ;               Note that some changes are here an others are in
                                0000    111 ;               BOOTDRIVR.ENH, since there are conflicts between VMS
                                0000    112 ;               changes and DS changes.

                                0000   116 ;
                                0000   117 ;       0215    TMH0001         Tim Halvorsen           10-Mar-1980
                                0000   118 ;               Mask off upper bits of PTE when constructing map register.
                                0000   119 ;
                                0000   120 ;       0214    KDM0092         Kathleen D. Morse       23-Jan-1980     16:40
                                0000   121 ;               Change VMB version number from 2 to 3.
                                0000   122 ;
                                0000   123 ;       00213   SRB0005         Steve Beckhardt         27-Nov-1979     16:10
                                0000   124 ;               Added code to support passing driver name from
                                0000   125 ;               boot driver to SYSBOOT.  Also added version # vector.
                                0000   126 ;                                                                       ;G:5
                                0000   127 ;       0212    SRB0004         Steve Beckhardt         31-Oct-1979     10:45
                                0000   128 ;               Moved all drivers into separate modules.  Added code
                                0000   129 ;               for connecting only the necessary driver.
                                0000   130 ;                                                                       ;G:5
                                0000   131 ;       0211    SRB0003         Steve Beckhardt         25-Oct-1979     16:40
                                0000   132 ;               Added console TU58 driver.
                                0000   133 ;                                                                       ;G:5
                                0000   134 ;       0210    CHF0001         Charlie Franks          23-Sep-1979     15:50
                                0000   135 ;               Added code and definitions to support RM80 bootable
                                0000   136 ;               system, includes: SSE and SSEI bit definitions, additions
                                0000   137 ;               to the MBAGEOM table and the MBA_DISK_DRUVER routine, and
                                0000   138 ;               the SSERROR skip sector routine.
                                0000   139 ;               Corrected byte count remaining update after encountering
                                0000   140 ;               a transfer error in MBA_DISK_DRIVER (convert MBA$L_BCR from
                                0000   141 ;               word to longword).
                                0000   142 ;                                                                       ;G:5
                                0000   143 ;       0209    SRB0002         Steve Beckhardt         13-Sep-1979     16:50
                                0000   144 ;               Added symbol EXE$GB_CPUTYPE (removed from module VMB)
                                0000   145 ;               so that it gets loaded into non-paged pool with the
                                0000   146 ;               boot driver.
                                0000   147 ;                                                                       ;G:5
                                0000   148 ;       0208    SRB0001         Steve Beckhardt         27-Aug-1979     10:30
                                0000   149 ;               Added boot device definitions ($BTDDEF).  Fixed CPUDISP
                                0000   150 ;               macro.  Added support for booting from console block
                                0000   151 ;               storage device.  Added 11/780 console floppy driver.
                                0000   152 ;               Changed boot value of R0 when booting from RL01/2 from
                                0000   153 ;               0 to 2.
                                0000   154 ;                                                                       ;G:5
                                0000   155 ;       0207    CHP0006         C. Peters               23-Jul-1979     16:16
                                0000   156 ;               Correct calculation of number of map registers needed.
                                0000   157 ;               Always invalidate one past the number required.
                                0000   158 ;                                                                       ;G:5
                                0000   159 ;       0206    CHP0005         C. Peters               20-Jul-1979     12:14
                                0000   160 ;               Add geometry of RM05 to MBAGEOM table.
                                0000   161 ;                                                                       ;G:5
                                0000   162 ;       0205    CHP0004         C. Peters               06-Jul-1979     14:06
                                0000   163 ;               Recode RK06/7 drive initialization code to correct bug
                                0000   164 ;               in RK07 handling.
                                0000   165 ;                                                                       ;G:5
                                0000   166 ;       0204    CHP0003         C. Peters               24-May-1979     14:24
                                0000   167 ;               Only invalidate the last UBA map register if the
                                0000   168 ;               transfer was page-aligned. Remove all code relating
                                0000   169 ;               to COMET-specific UBA map register format. All UBA
                                0000   170 ;               map registers are now alike. Delete definition of
                                0000   171 ;               storage for CPU_TYPE. Use instead a global symbol
```

```
                                0000   172 ;               EXE$GB_CPUTYPE Initialized by VMB to hold the CPU
                                0000   173 ;               identification code.
                                0000   174 ;                                                                   ;G:5
                                0000   175 ;       0203    CHP0002         C. Peters                   11-May-1979     13:20
                                0000   176 ;               Add code to invalidate the last UBA map register to stop
                                0000   177 ;               a wild transfer. This code is CPU-specific.
                                0000   178 ;                                                                   ;G:5
                                0000   179 ;       0202    CHP0001         C. Peters                   23-Mar-1979     8:40
                                0000   180 ;               Fill out module header. Add CPUDISP macro. Add local
                                0000   181 ;               symbol CPU_TYPE for CPUDISP's use. Add many comments.
                                0000   182 ;               Extract processor type from PR$_SID and store in local
                                0000   183 ;               CPU_TYPE. Find adapter type from CONFREG, and store in
                                0000   184 ;               general register. Initialize map registers in a CPU-
                                0000   185 ;               and adapter-dependent way. Determine which driver to
                                0000   186 ;               use based on adapter and device type. Add routine
                                0000   187 ;               header comments to MBA and RK06/7 driver code. Derive
                                0000   188 ;               device CSR address in RK06/7 driver from PR$_MAPEN
                                0000   189 ;               value used as index into RPB. Add routine header
                                0000   190 ;               comments to ECC routine. Replace .PAGEs with form feeds.
                                0000   191 ;               Add code and definitions to support RL02 bootable
                                0000   192 ;               system: includes $RLDEF, a test for the RL02 device
                                0000   193 ;               type, and the minimal RL02 driver code (written by C.
                                0000   194 ;               Franks).
                                0000   195 ;

Cross-reference output	5	00:00:00.10	00:00:00.19
Assembler run totals	1893	00:00:05.03	00:00:09.32

```
The working set limit was 2900 pages.
182865 bytes (358 pages) of virtual memory were used to buffer the intermediate code.
There were 80 pages of symbol table space allocated to hold 1509 non-local and 35 local symbols.
934 source lines were read in Pass 1, producing 99 object records in Pass 2.
26 pages of virtual memory were used to define 25 macros.
```

0000    33 ; FACILITY:     SYSTEM BOOTSTRAPPING
0000    34 ;
0000    35 ; ABSTRACT:
0000    36 ;
0000    37 ;       THIS MODULE PERFORMS LOGICAL BLOCK I/O FOR FILEREAD
0000    38 ;
0000    39 ; ENVIRONMENT:  KERNEL MODE, UNMAPPED, IPL=31
0000    40 ;
0000    41 ; AUTHOR: RICHARD I. HUSTVEDT    , CREATION DATE: 14-APR-78
0000    42 ;
0000    43 ; MODIFIED BY:
0000    44 ;
0000    45 ;       02      Bob Bergazzi    June 29,1983    Version 6.12
0000    46 ;               Adapted to run for supervisor.
0000    47 ;
0000    48 ;       V03-001 KTA0091         Kerbey T. Altmann       30-Mar-1982
0000    49 ;               Redo some entries in the file cache table.  Make the
0000    50 ;               page allocation part of BOO$CACHE_INIT a subroutine.
0000    51 ;               Divide it into two pieces.
0000    52 ;
0000    53 ;       V02-003 PHL0012         Peter H. Lipman         02-Aug-1981
0000    54 ;               Explicitly initialize the FILEREAD cache pointer.
0000    55 ;       Must not allow assembly time initialization since VMB can restart.
0000    56 ;               Fix PSECT so that VMB can overlay most of itself with
0000    57 ;       the secondary boot file.  Remove BOO$GL_RPBBASE.
```

```
0000     58 ;
0000     59 ;       V02-002 PHL0011         Peter H. Lipman         31-Jul-1981
0000     60 ;               The page at which the FILEREAD cache is located
0000     61 ;       should be relative to the RPB not absolute.
0000     62 ;
0000     63 ;       V02-001 PHL0007         Peter H. Lipman         14-Mar-1981
0000     64 ;               Extend parmeter list to FIL$RDWRTLBN to make it
0000     65 ;       possible to read more than one block at a time.  This
0000     66 ;       enhancement was made in conjunction with the cacheing
0000     67 ;       feature in FILEREAD.
0000     68 ;               Add new BOO$CACHE_INIT routine for VMB and SYSBOOT to
0000     69 ;       init the FILEREAD cache.
0000     70 ;               Move other common FILEREAD pieces into this module thus
0000     71 ;       avoiding them being in two places.
0000     72 ;               Add new BOO$IMAGE_ATT routine to fetch certain image
0000     73 ;       attributes from an image header.
0000     74 ;
0000     75 ;--
```

Pass 2	26	00:00:00.19	00:00:00.45
Symbol table output	2	00:00:00.00	00:00:00.00
Psect synopsis output	2	00:00:00.01	00:00:00.01
Cross-reference output	4	00:00:00.01	00:00:00.01
Assembler run totals	1353	00:00:01.11	00:00:03.17

The working set limit was 1900 pages.
26769 bytes (53 pages) of virtual memory were used to buffer the intermediate code.
There were 20 pages of symbol table space allocated to hold 197 non-local and 4 local symbols.
388 source lines were read in Pass 1, producing 24 object records in Pass 2.
12 pages of virtual memory were used to define 11 macros.

Macro library statistics

Macro library name	Macros defined
DISK$DS:[DS.LOCAL.RELEASE.WORK]DS.MLB;1	0
DISK$DS:[DS.LOCAL.RELEASE.WORK]DIAG.MLB;1	0
DISK$DS:[DS.LOCAL.RELEASE.WORK]PAMAC.MLB;1	0
SYS$COMMON:[SYSLIB]LIB.MLB;2	4
SYS$COMMON:[SYSLIB]STARLET.MLB;2	3
SYS$COMMON:[SYSLIB]STARLET.MLB;2	0
TOTALS (all libraries)	7

261 GETS were required to define 7 macros.

There were no errors, warnings or information messages.

The working set limit was 2400 pages.
54476 bytes (107 pages) of virtual memory were used to buffer the intermediate code.
There were 20 pages of symbol table space allocated to hold 352 non-local and 6 local symbols.
254 source lines were read in Pass 1, producing 31 object records in Pass 2.
13 pages of virtual memory were used to define 12 macros.

```
The working set limit was 2900 pages.
47658 bytes (94 pages) of virtual memory were used to buffer the intermediate code.
There were 10 pages of symbol table space allocated to hold 158 non-local and 11 local symbols.
310 source lines were read in Pass 1, producing 35 object records in Pass 2.
13 pages of virtual memory were used to define 12 macros.
```

Psect synopsis output	2	00:00:00.00	00:00:00.01
Cross-reference output	3	00:00:00.03	00:00:00.03
Assembler run totals	1789	00:00:04.59	00:00:09.09

The working set limit was 2400 pages.
191815 bytes (375 pages) of virtual memory were used to buffer the intermediate code.
There were 60 pages of symbol table space allocated to hold 1052 non-local and 9 local symbols.
192 source lines were read in Pass 1, producing 70 object records in Pass 2.
28 pages of virtual memory were used to define 27 macros.

Macro library statistics

Macro library name	Macros defined
DISK$DS:[DS.LOCAL.RELEASE.WORK]DS.MLB;1	1
DISK$DS:[DS.LOCAL.RELEASE.WORK]DIAG.MLB;1	11
DISK$DS:[DS.LOCAL.RELEASE.WORK]PAMAC.MLB;1	0
SYS$COMMON:[SYSLIB]LIB.MLB;2	4
SYS$COMMON:[SYSLIB]STARLET.MLB;2	7
SYS$COMMON:[SYSLIB]STARLET.MLB;2	0
TOTALS (all libraries)	23

1496 GETS were required to define 23 macros.

There were no errors, warnings or information messages.

Symbol table output	14	00:00:00.05	00:00:00.22
Psect synopsis output	2	00:00:00.01	00:00:00.01
Cross-reference output	6	00:00:00.37	00:00:00.58
Assembler run totals	2312	00:00:06.11	00:00:12.55

The working set limit was 2900 pages.
211409 bytes (413 pages) of virtual memory were used to buffer the intermediate code.
There were 60 pages of symbol table space allocated to hold 1168 non-local and 44 local symbols.
2120 source lines were read in Pass 1, producing 98 object records in Pass 2.
34 pages of virtual memory were used to define 32 macros.

Macro library statistics

Macro library name	Macros defined
DISK$DS:[DS.LOCAL.RELEASE.WORK]DIAG.MLB;1	18

Symbol table sort	0	00:00:00.09	00:00:00.08
Pass 2	24	00:00:00.26	00:00:00.43
Symbol table output	2	00:00:00.03	00:00:00.07
Psect synopsis output	2	00:00:00.01	00:00:00.01
Cross-reference output	4	00:00:00.06	00:00:00.16
Assembler run totals	1508	00:00:01.85	00:00:05.01

```
The working set limit was 2400 pages.
67430 bytes (132 pages) of virtual memory were used to buffer the intermediate code.
There were 20 pages of symbol table space allocated to hold 321 non-local and 13 local symbols.
227 source lines were read in Pass 1, producing 34 object records in Pass 2.
21 pages of virtual memory were used to define 18 macros.
```

Macro library statistics

Macro library name	Macros defined
DISK$DS:[DS.LOCAL.RELEASE.WORK]DIAG.MLB;1	1
DISK$DS:[DS.LOCAL.RELEASE.WORK]DS.MLB;1	7
DISK$DS:[DS.LOCAL.RELEASE.WORK]DS.MLB;1	0

0000    101 ;           11      FIXED 'CONTINUE' IN APT MODE
0000    102 ;           12      ADDED PROPER SPELLING OF "HEXADECIMAL".
0000    103 ;           13      CHANGED 'VRRUN' & 'VRLOAD' TO 'DSV$RUN' & 'DSV$LOAD'
0000    104 ;                   KEN CHAPMAN     06-APR-78
0000    105 ;           14      MADE 'COMPAT' COMMANDS CONDITIONAL ON 'VM11' DEFINED.
0000    106 ;
0000    107 ;                   NICK HOWGATE    09-JUN-78       VERSION 09 (ESSAA-4.03).
0000    108 ;           15      FIX APT ^C PROBLEM
0000    109 ;
0000    110 ;                   Roger Riggs     17-JUL-78       VERSION 10 (ESSAA-5.00).
0000    111 ;           16      Fix to let SUPERLINE do the prompt, clean up APT
0000    112 ;                   stuff in area of prompt.
0000    113 ;
0000    114 ;                   Roger Riggs     21-SEP-78
0000    115 ;           17      Insert support for new device selection commands.
0000    116 ;
0000    117 ;                   Roger Riggs     04-FEB-79
0000    118 ;           18      Insert "SET LOAD <filespec>" command for default load device
0000    119 ;           22      Add SHOW LOAD command
0000    120 ;           23      Fix SET LOAD, SET LOOP, SET LOCK interaction
0000    121 ;                   fix SELECT and DESELECT
0000    122 ;                   Fix SE AMBIGIOUS error
0000    123 ;           24      Raise ASTLVL in command mode to prevent AST delivery
0000    124 ;                   in command mode
0000    125 ;
0000    126 ;                   Roger Riggs     4-Sept-1979
0000    127 ;           25      Made command tree and command action routine global for APT
0000    128 ;
0000    129 ;                   Roger Riggs     6-Nov-1979
0000    130 ;           26      Changed version number on filespec to be decimal instead
0000    131 ;                   of octal.
0000    132 ;                   Changed MTPR x,PR$_IPL to call set so it's done in KERNEL mode
0000    133 ;
0000    134 ;           27      MARION BAGGETT  14-DEC-79
0000    135 ;                   ALLOW SETTING OF MEMORY MANAGEMENT ON OR OFF
0000    136 ;                   ALLOW EXAMINE AND DEPOSIT OF PROCESSOR REGISTERS
0000    137 ;
0000    138 ;           28      David Butenhof  09-Jan-80
0000    139 ;                   Fix exam/deposit of processor registers
0000    140 ;
0000    141 ;           29      David Butenhof  06-feb-80
0000    142 ;                   Be sure all possible AST levels are disabled to prevent
0000    143 ;                   interrupt-driven diagnostic from continuing after ^C or
0000    144 ;                   breakpoint.
0000    145 ;
0000    146 ;           30      David Butenhof  15-feb-80
0000    147 ;                   Add SEARCH operator flag
0000    148 ;
0000    149 ;                   Roger Riggs, 17-Jan-1980, Version 5.2
0000    150 ;           31      Corrected handling of command mode for APT, made sure
0000    151 ;                   it typed "DS> " after ^C and processing of any command.
0000    152 ;           32      Fixed saved IPL to save all 5 bits of IPL instead of just 4.
0000    153 ;           33      Remove disable of ASTs in CLI so that WAITMS works and
0000    154 ;                   ^C ASTs are delivered.
```

```
                                0000    156 ;           Dave Butenhof   30-jun-1980, version 5.5
                                0000    157 ;       34  Add HELP command in PARSE tree, and ACT_HELP action routine
                                0000    158 ;
                                0000    159 ;           Dave Butenhof, 02-oct-1980, Version 6.1
                                0000    160 ;       35  Add DIRECTORY command
                                0000    161 ;       36  Alter filespec parsing to recognise [000000] form as well as
                                0000    162 ;           [0,0] for UIC.
                                0000    163 ;
                                0000    164 ;           Dave Butenhof, 13-feb-1981, version 6.3
                                0000    165 ;       37  Change /SECTION:xxx so xxx can be symbol (inc. $ and _).
                                0000    166 ;       38  Add SET WIDTH command, and alter filespec parse to allow
                                0000    167 ;           subdirectories in user mode.
                                0000    168 ;
                                0000    169 ;       39  Dave Butenhof, 06-Oct-1981, version 6.5
                                0000    170 ;           Implement SHOW STATUS command
                                0000    171 ;
                                0000    172 ;       40  Jack Stansbury, 21-Oct-1981, Version 6.5
                                0000    173 ;           Added calls to QA$Main for the QA enhancement.
                                0000    174 ;           Also added .LIBRARY statements for $DIAG, $DS, and LIB.
                                0000    175 ;
                                0000    176 ;       41  Jack Stansbury, 22-Oct-1981, Version 6.5
                                0000    177 ;           Fixed truncation errors.
                                0000    178 ;
                                0000    179 ;       42  Jack Stansbury, 25-Oct-1981, Version 6.5
                                0000    180 ;           Many changes for the /QA qualifier on the
                                0000    181 ;           RUN and START commands, additional SET and SHOW
                                0000    182 ;           changes for the QA flags.
                                0000    183 ;
                                0000    184 ;       43  Jack Stansbury, 3-Nov-1981, Version 6.5
                                0000    185 ;           Major revisions to the parse tree. Renumbered all the labels,
                                0000    186 ;           moved things around, ... Also incorporated checks so that a
                                0000    187 ;           SET FLAG WIDTH 130 is not allowed (as it was before). Also
                                0000    188 ;           changed the error messages to mixed case. Also took out T_CRLF,
                                0000    189 ;           because it was not used. Most of these changes are not marked
                                0000    190 ;           since so much was done. Also made use of the new CLI$K_SLASH,
                                0000    191 ;           CLI$K_VALUE, and CLI$K_COMMA character values in calls to
                                0000    192 ;           $DS_CLI. These allow "/", ":" or "=", and ",", respectively,
                                0000    193 ;           with optional spaces on either side of them. They were added
                                0000    194 ;           to PARSE.MAR by Dave Butenhof. Also added /ADAPTER qualifier
                                0000    195 ;           to the SHOW DEVICE, SELECT, and DESELECT commands. This
                                0000    196 ;           qualifier
                                0000    197 ;           requires an adaptor name as its value. Also added SHOW DEFAULT
                                0000    198 ;           and SHOW BASE commands. Also added DCL-like printout of portion
                                0000    199 ;           of command line in error. That is,
                                0000    200 ;                   ?? error message
                                0000    201 ;                      \portion in error\
                                0000    202 ;
                                0000    203 ;       44  Marion Baggett, Jack Stansbury, 05-Oct-1981, Version 6.5
                                0000    204 ;           Enhanced the SHOW DEVICE AND SHOW SELECTED command to allow
                                0000    205 ;           the qualifier and print only the device type and name.
                                0000    206 ;           Added a new command SHOW SUPPORT to show the devices a diag
                                0000    207 ;           will support.
```

```
                     0000   209 ;       45      Jack Stansbury, 11-Nov-1981, Version 6.5
                     0000   210 ;               Changed the DS$PARSE call to DSX$SUPERPARSE. SUPERPARSE does not
                     0000   211 ;               return when it encounters EOL. Rather, it follows the
                     0000   212 ;               parse tree until it encounters CLI$K_EXIT. This fixes the
                     0000   213 ;               problem with SET BASE 0, where DS$PARSE saw EOL, and returned to
                     0000   214 ;               here with the NOTNUF flag still set. Thus, it was not continuing
                     0000   215 ;               in the parse tree, where it would have executed the ENUF action
                     0000   216 ;               routine, and then gone to EOL in the parse tree. DSX$SUPERPARSE
                     0000   217 ;               does continue, and thus will execute ENUF, and then go to EOL.
                     0000   218 ;               Also: changed the error handling and reporting. Established
                     0000   219 ;               different action routines for Illegal command versus Incomplete
                     0000   220 ;               commands. Checked return from DSX$PARSE and various CLI flags
                     0000   221 ;               and printed appropriate error messages.
                     0000   222 ;               Also: changed the DCL-like printout of the command line in error
                     0000   223 ;               to print the part of the line that was good. This was done
                     0000   224 ;               because of the strange results from doing it the previous way!
                     0000   225 ;               Also: added action routines ACT_OPTIONAL, ACT_REQUIRED,
                     0000   226 ;               ACT_IF_REQUIRED, ACT_IF_FILE_SPEC, ACT_BINARY, and ACT_VERIFY.
                     0000   227 ;               Also: added recognition of SET BINARY, SET VERIFY, CLEAR BINARY,
                     0000   228 ;               and CLEAR VERIFY. These are new control flags.
                     0000   229 ;               Also added ADVANCE action routine. It functions exactly
                     0000   230 ;               opposite of BACKUP.
                     0000   231 ;
                     0000   232 ;       46      Jack Stansbury, 13-Nov-1981, Version 6.5
                     0000   233 ;               Added CLI$K_CALL, CLI$K_RETURN, and CLI$K_BIFS to various places
                     0000   234 ;               in parse tree. Dave Butenhof added these new character codes.
                     0000   235 ;               They are to be used for one-level-deep subr calls. Also added
                     0000   236 ;               SUCCESS and FAILURE action routines to be used in with
                     0000   237 ;               the above. Also added a new DS command: EXIT.  Also altered
                     0000   238 ;               ACT_DO_CMD to avoid dispatching if CLI$L_COMMAND(R2) is 0; this
                     0000   239 ;               allows ATTACH to 'kill' the command when the /Adapter value is
                     0000   240 ;               bad. Also added the SHOW SECTIONS command.
                     0000   241 ;
                     0000   242 ;       47      Jack Stansbury, 17-Nov-1981, Version 6.5
                     0000   243 ;               Changed all BSBW's to JSB's.
                     0000   244 ;
                     0000   245 ;       48      Dave Butenhof, 18-Nov-1981, version 6.5
                     0000   246 ;               Add DEATTACH command, and typecodes in messages
                     0000   247 ;
                     0000   248 ;       49      Jack Stansbury, 21-Nov-1981, Version 6.5
                     0000   249 ;               Took out the DSQA constants and the calls to QA_MAIN.
                     0000   250 ;               It appears these will not be needed for the 6.5 DS version.
                     0000   251 ;
                     0000   252 ;       50      Dave Butenhof, 04-Feb-1982, Version 6.6
                     0000   253 ;               Use the new CLI$K_FILE parse code for filename/type parse
                     0000   254 ;
                     0000   255 ;       51      Dave Butenhof, 05-Feb-1982, Version 6.6
                     0000   256 ;               Add new command SHOW MEMORY.
```

```
                     0000    258 ;       52      Jack Stansbury, 18-Feb-1982, Version 6.6
                     0000    259 ;               Changed the HELP command parsing so that HSOW will not result
                     0000    260 ;               in the HELP command looking for DS command SOW! That is, if
                     0000    261 ;               spaces are not found after the minimum characters for HELP
                     0000    262 ;               (H in this case), then there must be an EOL. If not EOL, it
                     0000    263 ;               is an error. Also, I added the VSDP Supervisor command. This
                     0000    264 ;               is for CRD use. Right now, it simply prints "Command not
                     0000    265 ;               implemented".
                     0000    266 ;
                     0000    267 ;       53      Dave Butenhof, 09-Mar-1982, version 6.6
                     0000    268 ;               Change file parsing to accept subdirectories in standalone.
                     0000    269 ;
                     0000    270 ;       54      Dave Butenhof, 10-Mar-1982, version 6.6
                     0000    271 ;               Correct HELP parsing to accept 'H<CR>' as well as 'H '.
                     0000    272 ;
                     0000    273 ;       55      Jack Stansbury, 23-Mar-1982, Version 6.7
                     0000    274 ;               Added some macros (Br_If_Not_...) and took out some .LIST
                     0000    275 ;               statements.
                     0000    276 ;
                     0000    277 ;       56      Jack Stansbury, 10-Apr-1982, Version 6.7
                     0000    278 ;               Added support for running CRD-AutoTest on-line via the VSDP
                     0000    279 ;               CLI command.
                     0000    280 ;
                     0000    281 ;       57      Dave Butenhof, 13-Apr-1982, version 6.7
                     0000    282 ;               Add command to enable/disable generic name enforcement,
                     0000    283 ;               as backup. 'Set/Clear Enforce'
                     0000    284 ;
                     0000    285 ;       58      Jack Stansbury, 6-May-1982, Version 6.8
                     0000    286 ;               Added code in DS$Cli to not clear the ^C bit in the DS flags
                     0000    287 ;               longword if CRD-AutoTest was running. This is to allow ^C's
                     0000    288 ;               to be caught faster and easier by CRD.
                     0000    289 ;
                     0000    290 ;       59      Richard Brown, 19-May_82, Version 6.8
                     0000    291 ;               Addition of DEBUG command.  This involves placing the command
                     0000    292 ;               in the command line interpreter decision tree and adding an
                     0000    293 ;               action routine for the command.
                     0000    294 ;
                     0000    295 ;       60      Jack Stansbury, 24-May-1982, Version 6.8
                     0000    296 ;               Changed the "VSDP" command to "CRD".
                     0000    297 ;
                     0000    298 ;       61      Dave Butenhof, 25-May-1982, version 6.8
                     0000    299 ;               Restore poor SHOW MM command, which got kicked out by
                     0000    300 ;               SHOW MEMORY (note, however, that SHOW MEMORY did not
                     0000    301 ;               intend to do this, and should not be accused of bullying).
                     0000    302 ;
                     0000    303 ;       62      Richard Brown, 7-July-82, Version 6.8
                     0000    304 ;               Addition of /DEBUG qualifier to RUN and START commands.
                     0000    305 ;
                     0000    306 ;       63      Jack Stansbury, 15-July-1982, Version 6.9
                     0000    307 ;               Added code to call CRD Menu Test when the CRD command is typed.
```

```
                     0000    309 ;        64      Jack Stansbury, 24-July-1982, Version 6.9
                     0000    310 ;                Added code (commented out for now) that will check to see if the
                     0000    311 ;                CRD Menu Test command (CRD) is being called in user mode. If so,
                     0000    312 ;                it will print an error message. NOTE: this will have to be taken
                     0000    313 ;                out before the Supervisor is frozen for 6.9!!!!
                     0000    314 ;
                     0000    315 ;        65      Jack Stansbury, 8-September-1982, Version 6.9
                     0000    316 ;                Added three new commands: SET CRDTRACE, CLEAR CRDTRACE, and
                     0000    317 ;                SHOW CRDTRACE. These three all have to do with a new DSA bit
                     0000    318 ;                called DSA$V_CRD_Trace. This bit, when set, will cause the CRD
                     0000    319 ;                routines to print trace and debugging information for the user.
                     0000    320 ;
                     0000    321 ;        66      Jack Stansbury, 15-September-1982, Version 6.9
                     0000    322 ;                Added code in the ACT_CRD routine that clears the ^C handlers
                     0000    323 ;                and the ^C DS flag, and disable ^C's.
                     0000    324 ;
                     0000    325 ;        67      Jack Stansbury, 23-September-1982, Version 6.9
                     0000    326 ;                Changed the CRDTRACE qualifier to CRD/TRACE. The command are
                     0000    327 ;                now:
                     0000    328 ;                SET CRD/TRACE, CLEAR CRD/TRACE, and SHOW CRD.
                     0000    329 ;                Also changed the code
                     0000    330 ;                a bit at the activation of CRD - if CRD's initialization routine
                     0000    331 ;                returns failure, the DSR$Unload_CRD routine is now called.
                     0000    332 ;
                     0000    333 ;        68      Richard Brown, 27-Sep-82, Version 6.9
                     0000    334 ;                Changed default debugger name from DELTA to VDSDEBUG.
                     0000    335 ;
                     0000    336 ;        69      Jack Stansbury, March 3, 1983, Version 6.11
                     0000    337 ;                Added the SET CRD/DEBUG/TRACE command. This exact syntax
                     0000    338 ;                is required to minimize the number of people finding out
                     0000    339 ;                about and using this command. It turns on debugging mode in
                     0000    340 ;                CRD, and a LOT of output results!
                     0000    341 ;
                     0000    342 ;        70      Jack Stansbury, March 7, 1983, Version 6.11
                     0000    343 ;                Added the SHOW CALLS command. The routine is in the CRDImage
                     0000    344 ;                module.
                     0000    345 ;
                     0000    346 ;        71      Bob Bergazzi    28-March-1983   Version 6.11
                     0000    347 ;                Added the SET/SHOW PAGE command for video console terminals
                     0000    348 ;                in standalone mode. Routines are in PRINT.
                     0000    349 ;
                     0000    350 ;        72      John Ciukaj     4-April-1983    version 6.11
                     0000    351 ;                - Changed CRD Command Action routine (ACT_CRD) to
                     0000    352 ;                  allow online debugging of CRD AUTO Offline
                     0000    353 ;                  test package and offline initiation of
                     0000    354 ;                  CRD AUTO Offline by CRD Command.
                     0000    355 ;                - Changed references to CRD bits in DSA Flags to
                     0000    356 ;                  distinguish between online and offline.
                     0000    357 ;
                     0000    358 ;        73      Bob Bergazzi    8-Apr-1983      Version 6.11
                     0000    359 ;                Cleared Line_count when we put out a DS>, so that if we are SET
                     0000    360 ;                PAGEing, our first screen isn't wasted with stuff already seen.
                     0000    361 ;
                     0000    362 ;        74      Bob Bergazzi    May 16,1983     Version 6.11
                     0000    363 ;                Changed the order of the .LIB statements.
                     0000    364 ;
                     0000    365 ;        75      Bob Bergazzi    29-Aug-1983     Version 6.13
```

```
                        0000   366 ;          Added the SET MEMORY command.
```

```
0000   368 ;        76      Bob Bergazzi    20-Sep-1983     Version 6.13
0000   369 ;                Added the /TIME switch to the RUN and START commands.
0000   370 ;                Commented out for release 13 and 14.
0000   371 ;
0000   372 ;        77      Bob Bergazzi    21-Oct-1983     Version 6.13
0000   373 ;                Added the INITPCS command.
0000   374 ;
0000   375 ;        78      Domenic Andella 8-Nov-83        Version 6.14
0000   376 ;                Added branches to tree at GET_FILE_SPEC, and
0000   377 ;                START_AND_RUN routines. These modifications
0000   378 ;                are to allow '$' and '_' to be included in the
0000   379 ;                directory, filename, and file type when using
0000   380 ;                a script filename. SET LOAD cmd, LOAD cmd, RUN,
0000   381 ;                and DIRECTORY cmd. These changes are necessary
0000   382 ;                for VDS to run under VMS V4.
0000   383 ;
0000   384 ;        79      RE MUSE         8 MAY 1984      Version 7.0
0000   385 ;                allow device names of the form 'node$ggan'
0000   386 ;
0000   387 ;        80      Bob Bergazzi    May 21, 1984    Version 7.0
0000   388 ;                Added /WIDE switch to the DIRECTORY command so
0000   389 ;                that filenames will be displayed one per line.
0000   390 ;                This fixes the problem of truncation of long filenames.
0000   391 ;
0000   392 ;        81      Ted Salem       Aug. 2, 1984    Version 7.1
0000   393 ;                Added SHOW TESTS command which will print the number
0000   394 ;                and title of each test of the current diag. program.
0000   395 ;
0000   396 ;        82      Ted Salem       Aug. 6, 1984    Version 7.1
0000   397 ;                Added /NOALLOCATE switch to the SELECT command so
0000   398 ;                that a device does not have to be allocated.
0000   399 ;
0000   400 ;        83      Jim Shelhamer   20 AUG 1984     Version 7.1
0000   401 ;                Corrected fuctioning of EXAMINE for address A or F by
0000   402 ;                eliminating a 'backup' of the input string.
0000   403 ;
0000   404 ;        84      M. Baggett      27-Sep-1984     Version 7.1
0000   405 ;                Temporary fix to allow CRD to run online.
0000   406 ;
0000   407 ;        85      Ron Parker      1-NOV-1984      Version 7.1
0000   408 ;                Changed GT_MENU ... message to elimate 11/730 reference
0000   409 ;
0000   410 ;        86      Ron Parker      6-NOV-1984
0000   411 ;                Cleaned up ACT_CRD routine and added Menutest_Online
0000   412 ;                function.
0000   413 ;
0000   414 ;        87      M. Baggett      14-Nov-1984
0000   415 ;                Allow generic name formats for form '$m$ggan'/.
0000   416 ;
0000   417 ;        88      Jim Shelhamer   21-Nov-1984     Version 8.0
0000   418 ;                Add Boot command for starting attached processor.
0000   419 ;                Only works for Scorpio, all others return error message.
0000   420 ;
0000   421 ;        89      Amy Iorio       29-Nov-1984     Version 8.0
0000   422 ;                Add SHOW ENFORCE command.
```

```
0000   424 ;       90      Bob Bergazzi    2-Jan-1985      Version 8.1
0000   425 ;               Fix conflict between SET PROMPT and SET PAGE.
0000   426 ;
0000   427 ;       91      Ted Salem       22-Jan-1985     Version 8.1
0000   428 ;               Fixed /noallocate bug.
0000   429 ;
0000   430 ;       92      Jim Shelhamer   Jan 30, 1985    Version 8.1
0000   431 ;               Modified Boot action routine to give error message in user-mode.
0000   432 ;               Also, added dispatch via CMK to CMK$APBOOT.
0000   433 ;
0000   434 ;       93      Jim Shelhamer   Feb 20, 1984    Version 8.1
0000   435 ;               Modified Boot action routine to save node id of Ap
0000   436 ;               to be booted.
0000   437 ;
0000   438 ;       94      M. Baggett      20-FEB-1985     Version 8.1
0000   439 ;               Added commands SET ULTRIX,SET ODS and change file parser
0000   440 ;               to recognize ULTRIX structure.
0000   441 ;
0000   442 ;       95      Bob Bergazzi    Feb. 26, 1985   Version 8.1
0000   443 ;               Enable edit [76] (/TIME).
0000   444 ;
0000   445 ;       96      Bob Bergazzi    Mar. 4, 1985    Version 8.1
0000   446 ;               Disable edit 95.
0000   447 ;
0000   448 ;       97      Ted Salem       Mar. 5, 1985    Version 8.1
0000   449 ;               Added DUMP command - for the NI only.
0000   450 ;
0000   451 ;       98      Bob Bergazzi    Mar. 12, 1985   Version 8.1
0000   452 ;               ACT_MMON does a MOVL into a byte field. Fix.
0000   453 ;
0000   454 ;       99      Domenic Andella 28-March-1985   Version 8.2
0000   455 ;               Add CLI 'next' flag to be set upon receipt
0000   456 ;               of NEXT command for use by MP.
0000   457 ;
0000   458 ;       100     Jim Shelhamer   Apr 10, 1985    Version 8.2
0000   459 ;               Moved saving of AP node number to after it has
0000   460 ;               been parsed.
0000   461 ;
0000   462 ;       101     Ted Salem       April 30, 1985  Version 8.2
0000   463 ;               Added SET CPU xxx command for MP systems.
0000   464 ;
0000   465 ;       102     M. Baggett      20-May-1985     Version 8.2
0000   466 ;               Correct ULTRIX load string spec.
0000   467 ;               Added ULTRIX flags for key commands.
0000   468 ;
0000   469 ;       103     Domenic Andella 22-May-1985     Version 8.2
0000   470 ;               Added clear mp condition flag in ACT_run,
0000   471 ;               start,next, and continue routines.
0000   472 ;
0000   473 ;       104     M. Baggett      23-May-1985     Version 8.2
0000   474 ;               Fixed ULTRIX parsing.
0000   475 ;
0000   476 ;       105     M. Baggett      29 -May-1985    Version 8.2
0000   477 ;               Fix bugs in RUN and START file parsing routines.
0000   478 ;
0000   479 ;       106     M. Baggett      4-Jun-1985      Version 8.3
0000   480 ;               Corrected ultrix parsing.
```

```
0000    481 ;
0000    482 ;       107     J. Baranski     21-Jun-1985     Version 8.3
0000    483 ;               Added /BASE and /NOBASE qualifiers to SET BREAKPOINTS,
0000    484 ;               CLEAR BREAKPOINTS, EXAMINE and DEPOSIT.
0000    485 ;
0000    486 ;       108     A. Iorio        18-July-1985    Version 8.3
0000    487 ;               Added SET ASK_PROMPT, CLEAR ASK_PROMPT, and ACT_ASK_PROMPT.
0000    488 ;
0000    489 ;       109     J. Baranski     26-Jun-1985     Version 8.3

                        04D2    953 ILLEGAL:
                        04D2    954
                        04D2    955 ;
                        04D2    956 ; Illegal command error:
                        04D2    957 ;
                        04D2    958 ; This is called with the parse character pointer pointing to the illegal
                        04D2    959 ; character. This will usually be a character within an unrecognized
                        04D2    960 ; qualifier or parameter such as the "X" in "SET WIDTX". It is possible
                        04D2    961 ; for this to be called when a command is actually INCOMPLETE. This
                        04D2    962 ; happens, for example, in recognizing "SET BREAKPOINTS" but failing
                        04D2    963 ; to see any (required) spaces after the "BREAKPOINTS". If no spaces
                        04D2    964 ; are seen, ILLEGAL is called even though the next symbol could
                        04D2    965 ; actually be EOL (implying INCOMPLETE). If it is not an EOL, then there
                        04D2    966 ; is an illegal character (e.g., the "X" above) and the command is
                        04D2    967 ; ILLEGAL. If it is an EOL, then the required address is missing and the
                        04D2    968 ; command is INCOMPLETE. Therefore, EOL is checked below to make a
                        04D2    969 ; determination about the kind of error that has occurred.
                        04D2    970 ;
